>

Virtually every physical aspect of an antenna affects its impedance. Generally, though, a yagi type antenna is designed with a dipole as the driven element. Your antenna is 300 ohms because the driven element is (probably) a "folded dipole". A folded dipole looks like a rather narrow an elongated rectangle. One property of a folded dipole is that the "folding" is usually designed to cause a 4:1 impedance increase. Thus, a dipole which is typically about 73 ohms is transformed to about 292 ohms (300 ohms effectively).

Replacing the driven element with a conventional dipole is one way of avoiding the matching transformer. But, you should still use a 1:1 coaxial balun to convert from unbalanced to balanced.

On 27 Dec 1995 22:48:51 GMT Michael G. Reiney (mreiney@hevanet.com) wrote in rec.radio.amateur.homebrew:

: I have an Atlas 210X that works fine on 40 meters and up. On 75 meters, I can only
: get about 40W out of it.
: I hypothesize that if the high freq power out is ok, the transistors are good.
: The 80M filters are not tunable, so they've probably not been tweeked.

I obtained a 210X a couple of years ago, before a year-long trip to Nicaragua (where I operated as YN1ASW). I thought an older simpler rig might be more reliable and maintainable in a situation where I would have little test equipment and parts accessibility would be difficult. I checked the rig out at home with a regulated power supply, but when I got to Nicaragua I had a number of unexpected problems. First, my power source was a 12V battery charged by a solar panel, and I found the Atlas really needed the extra voltage available when the battery was under charge, the output power would fall off a lot when the voltage fell from 13.6 down to 12V.

More seriously, I found that there were serious instability problems if the rig looked into a reactive load. It would work fine directly into a dummy load, but through a tuner into the load or into a real antenna, whether through the tuner or not, it would break into parasitic oscillations as the drive was brought up to a critical level. I don't know exactly what frequency the oscillations were, but they tended to wipe out my housemates' VHF TV reception, and this put major constraints on my operating schedule.

I was able to get some control over the situation by putting a high resistive load (I think I used something like 1000 ohms, 2 watts -- I had a limited stock of resistors) across the input of the tuner. The idea was to have a high enough value that it would take a negligible amount of power at frequencies where the load looked like 50 ohms, but at other frequencies where presumably the antenna and/or the tuner looked like some kind of high-Q circuit this might damp it enough to suppress the parasitics. I was able to operate at reduced power levels this way, but any attempt to go for full power would result in parasitics again.

My operation was mostly on 20 meters, sometimes on 15 when it would support my skeds back to the US. I never was able to get more than about 50 watts out of the rig.

When I first obtained the rig I got a packet of info from Hi Manuals, which included a lot of info on various mods in early production versions of the Atlas, some of which I recall had to do with power output or stability problems. As far as I could tell my own Atlas was a late enough model to incorporate all the fixes, but it still gave me a lot of problems. My conclusion is that it just pushed too hard at the limits of the technology of its day, and that variations in the semiconductors probably weren't adequately protected against.

I don't know if any of this is relevant to your problems, but maybe there are some connections. I would definitely look for parasitics that may be robbing power from the operating frequency.

If anyone reading this has any comments on the problems I experienced I would appreciate hearing them. When I left Nicaragua in Dec. 94 I put the rig in storage there, as I expect to return there for another extended stint in the next year or two. But it would be nice if I could go back armed with some ideas about how to get the 210X to behave a bit better.

A couple of years ago I looked into this fairly extensively. 27 MHz
CB is a no - no as is commercial 50 150 and 450 MHZ bands. We ended up
using the 4?? MHz GMARS citizens band and I am not sure that this is
stirctly leagle.

If you are building a personal deveice I would look in to using directional
antennas you only need 5 db gain over the antenna you are using on 27 MHz
a 3 element Yagi-Uda on each end might do. This is not leagle for part 15
of the FCC rules as it is no longer defined as 100 mw but defined volts
per square meter and a derictional antenna will exced these levels.

If it is for personal use a ham licence is easy to get and 220 & 440
are leagle at any power level.

For a commercial device I don't know of a solution.

For and expermential device of any kind the FCC issues expermanetal
licences for one year at a time that are easy to renue. As I recall you
need to fill out a form and include a letter explaining what you are doing.

Good luck

9. Re: silver plating, help

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-01 00:00:00 UTC
From: Ian G3SEK <G3SEK@ifwtech.demon.co.uk>
Message-ID: <642326134wnr@ifwtech.demon.co.uk>
Source record: 108432

In article: <4c6na7$68j@ren.cei.net> dallen@cei.net (Allen Finne) writes:

: I dimly remember reading an article once describing the use of exhausted
: black and white photographic fixer as the electrolyte for silver plating.
: I do a bit of photograhy and have old fixer available. The fact I can't
: find the article only made me determined to figure out what the method
: outlined was. I have played around a bit and found that I can sucessfully
: deposit a nice even coat of silver on a piece of brass. My problem is
: mixed results getting the silver to adhere well. I have managed to get
: what I'd consider proper plating on an object, but later using the same
: parameters the silver film can be rubbed off. I have played with varying
: voltages, currents, and methods of cleaning the brass prior to plating.
: Here are the parameters I'm using:
: 1) Voltage source is a 1.5v dry cell.
: 2) Series resistance of 12k in circuit giving a current flow of 1
: milliamp or so.
: 3) Fixer saturated by loading it up with old photographic paper prior to
: plating.
: 4) Silver donor is an old piece of solid silver silverware.
: 5) Cleaning the brass with a scotch-brite pad then wiping down with
: alcohol to de-grease.

The article was "Safe, Sensible Silverplating" by J S Gurske, K9EYY in
'Ham Radio', February 1985. It works very well for copper and brass.

The main feature of K9EYY's method is that it doesn't use a conventional
bath of electrolyte. The plating is applied using electrolyte soaked into a
sponge which is tied onto the end of a carbon rod. The rod is connected to
the positive supply and the metal to be plated is connected to the
negative. The plating is then "rubbed on" using the sponge. If the
work-piece is really clean, the silver goes on easily to any desired
thickness until the electrolyte is depleted. Then you re-soak the sponge
with fresh electrolyte and carry on.

The most important electrical parameter is the current. K9EYY used 50mA
from a 6V battery in series with a 10k pot. He specifically warns against
using lower currents because the plating does not adhere reliably. For the
same reason, do not allow the sponge to touch the work-piece without the
power supply connected.

The rubbing action helps to consolidate the coating. The harder you rub,
the better the plating seems to be.

Obviously you need a drip tray to catch the electrolyte as it runs off the
work-piece, but there is no need for an assortment of plating baths of
special shapes and sizes. This is a huge advantage if your main hobby is

amateur radio, not amateur electroplating!

You can also save silver by plating the inside of coaxial cavities etc but not the outside. To plate the inside of a long tube, connect the carbon rod to an insulated wire, and tape the rod onto a stick. It is important to waterproof any bare copper connections, to avoid creating unwanted electrolytic cells.

K9EYY also describes how to regenerate the used electrolyte by dipping the carbon rod into the container and using some silver item as the anode (connections reversed, current 75mA).

If anybody in Continental Europe is reading this, the same electroplating technique works even better using the "Anreibe-Silber" mixture which you can buy at hamfests in Germany. This proprietary mixture is a tamer version of the cyanide solutions that the professionals use, so although the quality of plating is excellent I would not recommend it for anybody who is not trained in chemical laboratory techniques.

Unfortunately neither of these processes will plate over tin-lead solder without an electrolytic pre-treatment using cyanide solutions. You have to either use hard solder or plate the individual parts before assembly.

Hope this helps, Allen - happy plating!

From: tcmedlin@cris.com
Message-ID: <4c7egj$n3h@spectator.cris.com>
Source record: 108519

Does anyone know where i can find some inexpensive voltage tuned osc's? I have built several shortwave receiving converters to be used with the car radio. these have used crystals to date but i want to substitute the vto"s. vto's need to have outputs around 4-6 mhz, 6-8 mhz, etc or possibly a single one that would tune maybe 4-15 mhz or so. i am using a simple conversion and mixing this so output is connected to the car radios antenna and it is tuned to around 1000 khz.

the mixer is either a simple transistor or the ne-602.
thanks,
Tom Medlin, WA5KUB

18. 23 cm cavity and VCO/PLL

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-02 00:00:00 UTC
From: elendir@enst.fr
Message-ID: <4cbri6$2mk@tempo.univ-lyon1.fr>
Source record: 108436

Hi everybody,
I am still looking for 23 cm cavities (in Europe)...
However -
For the VCO part, I need a 1297 MHz design. Using a standard (or even TCXO) reference oscillator, I can hardly expect better than a 10^-6 precision, that is 1 KHz. This is too much.
Therefore I though locking my PLL on a reference signal, like the WWV (DFL in fact here). Does anybody have already made this kind of job ?

I thought to lock a XO at 3 MHz and then use it to further control the VHF VCO.
Starting with a frequency (153 kHz) better than 10^-12, can I achieve a VCO with a similar stability (< 1 mHz) ?

Thanks for any info
Vince, F5RCS

>I am trying to assemble my own HF medium power amplifier.

You might want to contact R.F. Electronics. They sell amplifier kits with power ratings of 300, 600 and 1,200 watts. You can buy them as kits or assembled, or just buy certain parts. For example, they list the PC board with parts list and instructions for $25.00 (300W). The 600W amplifier uses two boards ($45.00); the 1,200W uses four ($85.00). They also sell the various size heat sinks, 5-pole Chebyshev filter kit ($40.00 - covers 160, 80, 40, 20, 15 & 10M), and other parts.

I haven't done business with this company myself, but you can reach them at:

I built the kit and was quite impressed with it. Works as advertised and
only glitch was inserted by myself. It is now installed in the Jimmy
under the IC-706 and working against a mobile 4 band Hustler style
antenna on the rear bumper. What's the big deal, haven't seen anyone
complain about Yaesu, Kenwood or Icom not giving their stuff away.....

26. Mid-Atlantic Hamfests

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-02 00:00:00 UTC
From: cps@access.digex.net
Message-ID: <cps-0201961822340001@bab00110.slip.digex.net>
Source record: 108444
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc,sci.electronics

I used to keep a schedule online of upcoming hamfests in the Mid-Atlantic
(roughly Northern Virginia to New York) area. I'd like to do the same
thing this upcoming hamfest season.

I would appreciate it if anyone who knows of an upcoming hamfest would
email me with the details, and I'll add it to the list.

Even though hamfest season is still some time away, it's never too early
to start!

Thanks,

Chris N3JLY

27. !SUPER KEYER II - MYSTERY

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-02 00:00:00 UTC
From: brian.carling@acenet.com
Message-ID: <2a6.7302.546@acenet.com>
Source record: 108445

Many thanks for the tip, Tom.
I have the older Super Keyer, and I bet it does the same!
I rarely use the hand keyer mode, but I use the "Press 2 & 4"
method to tune up the antenna tuner.

TA> SOLVED!

TA> I built the now superseded CMOS SUPER KEYER II from the Nov.
TA>1990 issue of QST. I use it with a Bencher paddle and have been very
TA>pleased with its operation with the exception that occasionally it
TA>seemed to discharge the batteries pre-maturely.

TA> I have checked the battery drain several times in the past to
TA>confirm that the micro controller was in fact going into the power
TA>down sleep mode when left idle. Each time I did this test was after
TA>replacing the batteries and I observed the drain fall off to a few
TA>microamperes a few seconds after connecting the the new battery.
TA>Of course in the process of changing the battery I reset the
TA>controller and did the test in the normal power up keyer mode.
TA>Everything appeared fine and I remained mystified.

TA> Finally I discovered the cause. I had been away on a trip for
TA>five weeks and had just put in a new set of batteries prior to
TA>departure. Upon returning I found the batteries (3 AA alkaline cells,
TA>BTW) discharged. I remembered last using the keyer in the hand key mode
TA>for finalizing my ladder line antenna tuner adjustment (conveniently
TA>done with momentary ~key down~ in the hand key mode). I had left the
TA>SUPER KEYER in the HAND KEY mode.

TA> I have found that my SUPER KEYER II does not switch into power
TA>down when it is left in the HAND KEY mode. I wonder if anyone
TA>else has identified this in the past or if anyone knows of a change of
TA>firmware in later chips that corrected this bug? I wonder if the new
TA>version III has a similar problem?

28. CMOS SUPERKEYER II CURRENTS

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-02 00:00:00 UTC
From: tom.alldread@minfox.com
Message-ID: <9601031820348672@minfox.com>
Source record: 108446

Greetings:

Further to earlier post on this subject I have recorded the
current drawn by my CMOS SUPERKEYER II in various modes.

I connected a digital mA meter in series with my keyer
battery to measure the current drain and the following is the
test results (with the sidetone monitor speaker turned off):

KEYER MODE SENDING DASHES: 3.35 milli Amperes
KEYER MODE SENDING DITS: 3.22 milli Amperes
KEYER MODE IDLE-FIRST 3 SECS: 2.64 milli Amperes
KEYER MODE IDLE-AFTER 5 SECS: 0.9 micro Amperes
(IE: 0.0009 milli Amperes)
HAND KEY MODE - KEY DOWN 3.45 milli Amperes
HAND KEY MODE - KEY UP 2.53 milli Amperes continuous
FUNCTION MODE 2.61 milli Amperes continuous
TRANSMIT TUNE 3.19 milli Amperes continuous
? INTERROGATE MODE 2.72 milli Amperes continuous

With the monitor speaker on in the ~hand key~ mode and key down
the current increased to 18.45 milli Amperes.

As shown the only time my keyer will go into its power down
sequence is when it is in the regular ~keyer~ mode.

Generally the CMOS SUPERKEYER II has served me very well and I
am pleased with it. Now that I am aware of its power down
characteristics I will be careful to ensure that I leave it in the
~keyer mode~ when not in use to preserve the battery life.

In the event that a new version of firmware is written
possibly a suitable watch dog timer could be incorporated to kick the
keyer out of the special modes after an appropriate delay. To
help preserve battery longevity for those that regularly use the keyer
in the ~hand key~ mode possibly a second power down sleep sequence could
also be provided for that mode of operation.

It would be interesting to hear from others that make similar
power drain measurements on their CMOS SUPERKEYER II keyers to determine
if the characteristics were improved in later versions. Mine is probably
has the first firmware release as I built it shortly after the article
was published in November 1990 QST.

Message-ID: <4cchsd$79s@hpcvsnz.cv.hp.com>
Source record: 108448

Hello All,

If I have posted this to the wrong newsgroup, please don't flame me - I am new at this!

I have an older video camera left over from the family entertainment center which another local ham wants to use for ATV work. The camera is (for reference) a Minolta K-520S, and is the kind with the cord which connects to a separate VHS tape deck. The connector is ten pins.

I understand that the above connector arrangement was "semi-standard" for this sort of camera. Does anyone have information on the pinout for this camera, or know where I could find same?

Please reply to me at gulseth@spk.hp.com. Thanks to all!

I am in desperate need of a 50 or 60 db WR-42 fixed Waveguide attenuator as well as a 0 to 40 or 50 db WR-42 variable Waveguide attenuator.

These are being used to set up some 18 Ghz Microwave Radios. My usual source for these type of components has gotten out of the as they put it, "Plumbing Business"

I only need them for a short period of time, I will pay for shipping in both directions and will reward you both financially and with unending gratitude!!!

Please respond via:
ngjere@ktca.org

If this device is being used in the Amateur Radio Service there is frequencies in the 6 meter band reserved for radio control aircraft (if that is what you are doing). Also check frequency listings for garage door opener and etc freqencies (up about 300mhz)

Well...about 90 miles south of Metro DC is the annual Frostfest in
Richmond.

Held at the Showplace...3000 Mechanicsville Tpk, Richmond, VA
Sunday, 1/21/96 from 8:30 to 3:30.

Take I-95 south to I-64 East (Exit 75) to US 360 East (Exit 192).
Showplace is 1/2 mile on the left.
Parking is free, admission is $5.00. No discounts for advance tickets.
Licensing exams are usually conducted the day before. Not sure what is
planned for this year.

Info is available through the voice mail service of the Richmond
Amateur Telecommunications Society at 804/739-2269. Enter box number
3378 (FEST) for general information and table reservations.

Major retailers are expected there (most notably HRO, but there are
many others), a number of manufacturers (not sure who has committed
yet), and ample flea market space. Computer vendors will also be
there.

Hope to see you there!

E-Mail me if you need more info.

PIN Function
1 Camera Video Out
2 Camera Video GND
3 View Finder Video In
4 View Finder Video GND
5 NC
6 Pause Control Out (Useful for TX Control)
7 Camera Audio Out
8 Camera Audio GND
9 DC GND
10 +12V Power

This is the pinout for my Sony 10 pin camera. It is somewhat standard.
A volt or two superimposed on the viewfinder video in line switches
the viewfinder from internal (camera) video to external (tape machine)
video for playback.

MCM Electronics has the 10pin female connectors if you are rolling
your own power supply/interface. 800-543-4330

>I don't mean to sound like a "wet blanket", and I don't know your age, mine is 52. But, I remember the exciting time when, with almost nothing at all, one could get on the air with something he or she built. Or, if you were intrested in just building an electronic project from Ppopular Electronics, you were able, because at the age of 12 or 13 you didn't have the money to by that one part that could only be bought from that special place, who ever or were ever it might be.

Have you ever longed to build something electronic at the age of 12 or so, and had no money, but the author gave you a way to do in in the article, like the code for the chip, or the turns count and size of the coil.

I believe,(This is only me talking.) and I am a member of ARRL and you have published 2 very popular articles I wrote, at least my fan mail said so, that QST is no longer a member publication devoted to ham radio, FOR THE LOVE OF IT, but has gone into business, targeting those people who

would buy more magazines, (Your on the news stand now.) books, and other offers the ARRL has, and has geared it QST publication toward them.

Who are those people, (Me talking again.) thay are people who never grew up in ham radio scrounging a part or a who rig full of parts to get on the air, and if the truth be known, computer have the interest of the young people, not ham radio. I can talk any were in the world on internet who needs a radio.

Those are the people targeted by QST. We all see the QRP articales, about the only rig that can be built any more, if one can find a variable capacitor. Have you even seen a dealer advertise a line of variable capacitors in QST or any were elce. I have been in hard electronic repair for 35 years, and I can fix hundreds of things not made anymore, or will never be made again. Why, becasue it all gone to software, and QST won't publish it so we can use are new skills and try and program our EPROM or processor chip, we have to buy it, just like Popular Electronics.

When is the last time we saw a 75 watt Novice rig in QST built and presented by the ARRL lab. Packet is the revolution for those with interest in computers. I can use computers, and repair them, thank you. I tried packet and sold it. My time is better spent on something that is real time then waiting on the postman.

I, and people like me, are no longer the interest of the ARRL, or QST. I love ham radio. It has gotten me good jobs from the skills it has given me. I have talked to lots of people. Years ago thay all built something, today most do not even own a good soldering iron. QST know that. I, and the 12 and 13 year olds are no longer the target, the kit builder, and the buyer of new equipment is because there in no money in me and a 12 year old. There never has been any money in me and my kind in ham radio because we build from parts, which there is no money in.

We are the ones that some QST articles have made fun of because we see a good deal in a broken radio, and can fix it, or see the value in a pile of junk that know one elce can recognize, and are no longer recongnized by QST.

That is why the missing chip code to the ATU article is importent. Not because you can build the unit by odering the part, but because you can not say, on the air, I programed the chip myself from and article in QST.

Hi, I need help designing a simple circuit. I have two audio outs (A and B). A is stereo and primary, B is infrequently used. I'd like a circuit that would allow me to plug in one set of earphones and monitor A, but when B comes on to switch to it then back when B is silent - it could be to just one channel of the headphones to simplify.

I'd like it to be self powered.

Thanks in advance.

From: rst@tetrault.com
Message-ID: <rst-0301961356490001@squaw-d121.sierra.net>
Source record: 108462

Recent postings about the 723 et al looking for low noise regulators, prompted me to go back into the databooks.

Looking at the National specs for the LM723, while RMS noise is specified, it is only spec'd as typical, with no maximum.

The Motorola databook for their TL431 claims low noise, and even gives a Noise Spectral Density graph, but nowhere do they actually specify even the typical noise characteristics, much less the max values.

On the other hand, the National LM369 series of precision references is fully spec'd and guaranteed 30 microVolts RMS maximum, typically 10 microVolts, unfiltered. Adding a .1uF film cap brings it down to 4 microVolts, and more is better, up to 1uF. Also, the LM369 has ppm stability for line, load and tempco.

Unless there is hard data that no 723 exceeds their typical noise spec, ever, my money will continue to go with the LM369, though it is more expensive and dictates a discrete design to the regulator, for low current demand oscillators, a 30 milliampere buffer is a trivial exercise...

Bob T

How much noise would a 30mA buffer contribute to the LM369 output?
Is the LM723 spec taken using the integral pass transistor?

I have bought several homebrew amplifiers. Usually projects derived from
publications (my interest is in VHF/UHF high power amps). In this case there
is little alternative to homebrew. Power amps are simple enough you can
visually tell the condition (except for tubes), and it's not too hard to
figure out the value of parts and labor and get documentation (in the form
of original publications). A project faithfully built to published docs
(such as a K2RIW amplifier) I think is worth a good price.

Homebrew solid state gear has for me generally been a disappointment and I
tend to avoid it unless it's a specialty for me (tiny QRP, etc., again with
some related documentation).

I _always_ avoid "homebrew" computers and related parts - too hard to know
if it's working without GOOD recourse.

48. PCB for RF and linear ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-04 00:00:00 UTC
From: opworld@worldnet.fr
Message-ID: <137cc$16cf.282@news.ak.net>
Source record: 108376
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

Hello,

I bought a few years ago LAYO. I followed (and paid a lot) every upgrade. Today I think I made a wrong choice. The evolution of this product is poor. It's very borring to use because you have to translate between two products (one product for drawing and another for design PCB). For linear circuits with ground plane... I stop here, it's become incredible !

1) I have linear and RF circuit to design : Is there a freeware, I can download to quickly do my work ?

2) Is there an interesting product ? (with a concurrential offer ?)

Thanks for help

Hi,

Looking for POS150 spec's. It's a VCO.

All informations about VCO for 80-110 frequencies with very low
distortion and low harmonics are welcome.

Shawn, as I recall the Bearcat 210, it is an FM-only receiver, as is the RatShack Weatheradio, rendering either useless for your purpose of receiving SSTV.
A simple direct conversion (DC) receiver would be a better low cost solution. Ramsey Electronics' model HR-20 is a 20 meter DC receiver kit for 30 bucks that should do the trick for you. Of course you might be able to buy a used older receiver at a swapfest too. What you want is a receiver that will receive SSB and CW to get the SSTV you need. Some (few) scanners have SSB/CW capability but they aren't cheap. Digital receivers such as the Sony 2010 and similar, Uniden 2026, Radio Shack DX-440, Sangean ATS-803 etc all have this function as well as many others of course and for much more than 30 bucks.
I have no connection at all with Ramsey except that of an occasional customer.
If you have access to Radio-Electronics, 73, QST back issues at a local library there are occasional articles for circuits similar to the Ramsey kit using the NE602 converter IC. Most recent ARRL handbooks present simple similar circuits that can be easily modified to suit your needs.

Hi,

I'm curious how the software works. Does it just change something at
random and see what happens, and if SWR gets better keep going in that
direction?

If you make a large load or band change how long does it take to tune?

The POS-150 is a MiniCircuits part number. I don't have a data sheet here at home, so I can't immediately quote the specs. It's almost impossible to subscribe to an electronics trade journal in the US and NOT have a MiniCircuits catalog, tho.

If you can't find it elsewhere, email and I will look it up for you.

Over 25 years ago, I worked on the Collins 490T antenna tuner when I was in the Navy. That box will tune a "random wire" antenna pretty much anywhere in the 2-30MHz range. It has no processor: it uses a rather small array of silicon controlled switches to sequence through its procedure. It is rated to tune a new load within 5 seconds, but our rule of thumb was that if it took over a second and a half, it likely had a problem. It used motor-driven vacuum variables and inductors. It did have both phase and SWR sensors. Anyway, the point is that you don't really need a processor to accomplish the tuning procedure, though that's probably the easiest way to do it these days. But clearly, in the case of the 490T, the algorithm wasn't terribly complex, and AT LEAST there should be no reason for not providing plenty of detail about the procedure, if not the code itself.

: So, when I saw the article, the first thing I looked for was the source code.

Me too. In fact, I still have no trouble scrounging all the parts I would need to do any of the basics of getting on the air, though I'm also interested in playing with things like DSPs, and I'm willing to pay for inexpensive evaluation boards that provide assemblers and similar tools.

But on the other side of the coin: I sometimes get printed circuit boards that are loaded with parts that would be quite useful to someone homebrewing RF or audio equipment. I've found that I have trouble even _giving_ these things away. My conclusion is that there must just not be _that_ many people experimenting with electronics and homebrewing things, or else all those that are are getting all the free parts they need.

>...What's the big deal, haven't seen anyone
>complain about Yaesu, Kenwood or Icom not giving their stuff away.....

The "big deal" to some of us is that the tuner was presented in a build-it-yourself article, not in a product review. It's disengenuous to publish a schematic for the whole world to see and at the same time decide the source code must be kept secret. In fact, some magazines require that source code be made available, via BBS or other methods. The greatest value in DIY articles is probably not in the constructing of exact clones, but in seeing how somebody else solved a problem, and in providing a starting point for trying something new. Many people might be interested in trying a similar circuit with a different micro installed, or in running the tuner from a PC, just as others would use different relays or other components. However, with the micro presented as a black box, we learn nothing of how the device works. We are presented with a hardware schematic but not with a software schematic. For those who say that it's unlikely that anbody would program their own chip, I'd just say look at the number of assemblers, compilers and programming devices on the market, compared to, say, the number of sources for toroid cores. The ability is there.

I believe one of the authors has written that they did offer a detailed flowchart when they submitted their article, but QST chose not to print it. If that is the case then I think the authors are partially exonerated and QST is partially to blame. As I said, if they wanted to do a product review they should have called it a product review.

Excellent comments. I, too, am one of those people who grew up scrounging parts from old TV's and radios. I enjoy thinking about, planning, obtaining parts for, and building things much more than operating them.

I have been contemplating, for a few years, a home-brew ATU. Coincidentally, I planned to use the Motorola 68HC11 micro-controller chip, just like the one in QST, because I have the development board for it.

The stimulating exercize, in my opinion, is developing the algorithm to iterate to the match (with the L network, there's only one). I had thought that both the phase and magnitude of the impedance (seen by the ATU) would be needed to drive the iteration routine for both the capacitance and inductance. Not having the 6811 source code, I don't know how the ATU in the article works, but it looks like only the SWR is used. One can only guess that a 'brute-force' search is used until an acceptable value of SWR is found.

So, when I saw the article, the first thing I looked for was the source code. When I saw that it wasn't available, I was no longer interested.

61. Ham Gods: interesting questions on the nature of Hetrodyning/Spectrum Analyser guts

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-04 00:00:00 UTC
From: fj91@dial.pipex.com
Message-ID: <4chl02$1te@soap.news.pipex.net>
Source record: 108389

Hi -

Our company is looking at producing an inexpensive Spectrum Analyser, from as near DC as we can get :) to 1GHz or so. I'm from a digital background, but I've studied the necessary techniques as carefully as I can. But there are many things that are mysterious to me, Gods of Ham Out There.

Things I know:

* We need to use hetrodyning for the same reasons as radios
* We may need to have multiple mixer 'channels' to deal with the enormous frequency range, as varactor-tuned VCOs have limited range
* We can use multiple IF stages, subsequent ones 'tuning in the previous stage's bandwidth' with decreasing IF filter bandwidth as we go
* There exists nice cheap mixers like the NE602 and the NE600
* There exists nice cheap 10.7Mhz ceramic filters with 50kHz bandwidth (hurrah)
* There exists nice cheap 455kHz 'IF Can' filters with 4kHz bandwidth (hurrah)
* The selected IF (which depends on desired bandwidth) goes to a log amp and a detector, followed by an A-D convertor in our case

Top three things I don't know and would like pointers on :)

* If I feed the same frequency sine wave to the RF and LO sides of a mixer, I know I get double the frequency (ie, the second harmonic). But the rules of mixing seem to indicate I will also get some kind of component at DC, ie f+f=2f, and then f-f=0. Assuming you are not already choking on your beer with laughter at this newbie blunder, why then does one need a detector? Why can't I run the LO at the frequency I'm interested in, slug the mixer output with some brutal filter that suffocates anything past a few Hz and accept the result as reflecting the RF energy at the frequency of interest? (is it 'cos the output of the mixer is

AC-coupled internal to the mixer? :( ) I really really _really_ wish I could do this, because then I end up with a tracking generator for free.

* My evil, cunning plan for generating DC-1280MHz via my evil, cunning version of DDS involves a fixed frequency divider chain starting at 640MHz (it divides by two each time). From 160MHz down, I see I can do this with 74AC74s or whatever, with a filter to kill the harmonics in the resultant 'digital-style' edges. However, how can one divide 640MHz and 320MHz by 2? Not with anything beginning 74, for sure :(. I have an alternative 'plan B' proposal: start the chain at the 74AC-friendly 160MHz, and use the mix-the-same-signal frequency-doubling techniuqe to synthesize 320 and 640Mhz. However, the division from a single 640MHz frequency 'Mecca' sounds like it should be more accurate.

* A mixer like the NE600 claims only to work from 800MHz to 1200MHz. The otherwise helpful Philips data acts as if DC-799.999999Mhz are the work of the Devil, and no self-respecting cellphone designer would want to know about them. However, Philips, we are not all designing cellphones out here! Does anyone have an opinion as to whether, the evil DDS technology notwithstanding, I can use a single NE600 to cover my range of ~DC to 1.2GHz?

Gods of Ham: I salute you for reading these humble puzzlements. If you know things, please spare a moment to send this sinner on to the path of righteousness.

-Andy

on 4 Jan 1996 00:39:44 GMT TSJV87A@prodigy.com (Ernest Hansen)
writes:

-Does anyone have any advice, recomendations, information or pointers to
-information on converting cellular telephone equipment to the 902 MHZ
-amateur band? Is it possible? Post or Email me at TSJV87A@prodigy.com.
-Thank You Very Much.
-
- ERNIE TSJV87A@prodigy.com

Difficult and expensive. It would be cheaper to just buy the 900MHz
rig. You have the problems with the very sharp filtering in the
transmit and receive portions of the phone. Remember, the transmit
and receive at the same time just like a repeater. They have VERY
sharp bandpass filters to prevent the transmitter from desensing
the receiver. You would have to change both of these filters. You
would then have to change out the transmit module that is specifically
designed to transmit in the 830MHz band. Most of these modules
use direct digital synthesis that is controlled by CPU by specific
"memory addresses." ie. 10100111 might mean "transmit on
832.875MHz" so the transmit module transmits on only a specific set
of frequencies. The same is true for the receive module. Now if you
can find one of the old (10+years) phones you might be able to
modify one of those. They had a separate digital synthesizer and
signal generator. Many of them used Z80 CPUs.
Good luck

For new designs, I am using a Harris HFA3101 Gilbert cell as a replacement
for the 1496. It is almost a pin for pin functional replacement, but
requires less bias voltage and current and has an order of magnitude or
so more bandwidth.

Most homebrew gear has no documentation, no support, and may be one of
a kind. Now used commercial gear may have no documentation too, but you
can usually find some, either from the manufacturer or from other users.
If the commercial gear is relatively recent, it may also still have
manufacturer support and parts available. Even if it is old, there are
likely thousands of other units out there as points of potential salvage
(see Micor or GE Mastr). Your homebrew offering has none of this. It
is like an orphaned piece of equipment from a defunct company. Unless
there's some collector value, people won't usually pay more than salvage
prices for that type of gear.

Now that should give you an idea how to increase the value of your
homebrew gear on the market. Make sure there is full documentation,
operating instructions, schematics, theory of operation, parts lists,
and even X-ray view board layouts if applicable. This should all be
nicely organized and bound, and included with the equipment. The
equipment will still be an orphan, but it will be a more valuable
orphan because of the information that would otherwise have to be
puzzled out by the buyer. (This is *very* important to me.)

As to builder skill, I treat this somewhat the same way I would
when buying a used Heathkit. I look at the unit and see how
professional it looks. Someone who has taken the time to make
up professional looking panels, who has soldered neatly, and
who has paid attention to wiring dress, probably also took
some care in design. Therefore I'm more likely to pay a good
price for something that *looks* like quality equipment than
I am for something that looks like Rube Goldberg haywire junk.

If the seller will additionally be willing to demonstrate the
equipment, and/or offer a brief warranty period, then I'm *much*
more likely to pay him a better price.

In short, the closer your homebrew gear approaches commercial
standards and practices, the closer I'm willing to pay comercial

prices.

70. Linear Transverters

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-04 00:00:00 UTC
From: MUENZLERK@uthscsa.EDU
Message-ID: <01HZLVDOBBNM005MMF@uthscsa.edu>
Source record: 108398

I am planning to buy a transverter (2 meter) that requires
1mw to 10mw input. My rig can be turned down to about
5 watts output. Should I just build a 20db attenuator or is
there a better way?

thanks

Kevin, WB5RUE

There are some potential pitfalls when "turning down" a HF rig to act as an exciter for a transverter. While signal will be less, amplifier noise won't. So you'll be transmitting a good deal of broadband noise at the transverter output. And most solid state PAs will show a greater percentage distortion as their drive is reduced from design values. So IMD and splatter may be worse. And many solid state PAs will show reduced efficiency at low drive. These factors can add up to a crappy signal on the air through the transverter.

There are two other ways which are generally better. One is to run the rig at full power into a dummy load and use a 40 db coupler to bleed off a 1 mW sample from a 100 watt exciter. This will give you a signal *cleaner* than you'd normally get on HF since the fixed level broadband noise will be attenuated, and the distortion characteristic will be at design values. This does waste power, of course.

The second way is to go into the HF rig and take power out from the driver stage where the levels will be more nearly what you want to drive the transverter. You can then disable the PA entirely, and save the idle current it normally draws. This gives you a clean signal, and saves power for portable operation. I prefer this solution.

Of course, if the transverter IF port isn't split, you're going to have to come up with some sort of TR circuit to switch out any attenuation you may have in there for transmitting. This is one reason I prefer transverters with split T and R IF ports, and HF driver radios with same.

Source record: 108403

I've found this to be somewhat true in my area (Dallas). I have sold a few HB items (QRP transmitters, a keyer, a small d-c receiver) and a number of commercially built rigs with modifications (some minor, some major). As I recall, in nearly all of these cases, the buyers were themselves fairly savvy about homebrewing and modifying equipment, and they were able to look at and recognize good workmanship and use of quality parts (both of which I take pride in when I build something). Homebrew gear on a swap meet table draws a lot of "tire kickers" and "question askers", but only the "right" buyer will buy it. And, as I said, the right buyer is usually a home-brewer himself. I only sold one semi-HB item over the Internet, and the buyer wanted it specifically for the parts (I actually stripped it, sold him what he wanted, and kept the enclosure and unwanted parts for myself).

I guess you're considering offering some HB items for sale? Whatcha got? I'm not afraid to buy HB gear if it's done right!

From: Jim <jdd@cellnet.com>
Message-ID: <4chf6s$gl9@mirrors.cellnet.com>
Source record: 108404

Hi folks,

I too have qualms about using QST articles as a profit making vehicle for the authors and kit makers. But my guess is that QST doesn't have much choice due to a lack of good article submissions from hams with only the advancement of the hobby in mind.

We, the readers of this news group, are the builders and innovators of the ham community. If we don't write these articles, QST and the other mags can't print them! We need to get off our tails and get on it, or we have no right to complain. I certainly do NOT exempt myself from this, and I've got something on the bench now. I hope to write it up...

Good luck!

From: myers@West.Sun.COM
Message-ID: <4ch6gf$56k@abyss.West.Sun.COM>
Source record: 108405

One technique I've used and seen used elsewhere to reduce the noise
on a power line is to insert an emitter follower into the
power line. The base of the emitter follower is biased from a
resistive voltage divider attached to the collector (which forms
the "input"), and a fairly large filter capacitor in parallel with
a smaller one is attached from the base to ground. I've never
actually measured the noise reduction of this arrangement, but
SPICE suggests it is significant. I believe it is fair to
analyze this circuit as an RC low pass filter with an emitter
follower added to reduce the output impedance.

>much prettier figures at 2 V output than at 36 V output.

The TI and National Semi databooks both list the 723 as having a
typical output noise voltage of 2.5uV RMS in a test configuration
given as Figure 1 in both datasheets. The value of the reference
voltage divider resistors is given Table 1 in both datasheets;
the output voltage is 5.0V.

Interestingly, while both datasheets list 2.5uV RMS as the typical
noise voltage with a 5uF capacitor at the error amplifier input,
the National sheet lists the typical noise voltage as 86uV RMS
without one, and the TI sheet lists 20 uV RMS. While the Motorola
MC1723 sheet lists the same conditions and values as the TI sheet,
it omits the table specifying the resistor values used to achieve
the 5.0V output.

80. SIMPLE SIMPLEX REPEATER....HELP

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-04 00:00:00 UTC
From: tcmedlin@cris.com
Message-ID: <4cf79j$559@spectator.cris.com>
Source record: 108464
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I recently built the simple simplex repeater as described in 73 Amateur Radio Today, nov 1995 issue but i have one problem that i need help resolving. if the receiver receives a signal for about one half second or less, the simplex repeater keys up for the entire 20 second period then drops out. any received signal more than about a half second operates it correctly. example: if the receiver receives a signal for 5 seconds, after the rec signal drops, it then retransmits this signal for 5 seconds and then resets or drops out. it is only the very quick keying pulses that lock this thing up.

the repeater is based on the ISD1000A voice record/playback IC which can be found at radio shack and about 30 simple parts. this chip is designed to record a maximun of 20 seconds.

there are 2 rc delay circuits which i have tried to adjust but this does not seem to help. I dont think the problem is power related as i have a good supply, and plenty of filtering and bypassing on it.
If anyone can help, please email me at tcmedlin@cris.com

thanks,
Tom WA5KUB

81. Re: 2M T/R relay plans?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-04 00:00:00 UTC
From: Jim Devenport <jdevenport@lanl.gov>
Message-ID: <4cfepa$bt6@newshost.lanl.gov>
Source record: 108465

It's been a while since I homebrewed my VHF T/R relays but I found some SPDT reed relays in a surplus catalog (cannot remember the source) and it was a fairly simple matter to enclose them with braid from RG58 or RG59 and wind a solenoid coil around the outside to apply the 12VDC switching voltage to. Of course the connections to the reeds and shield must be kept as short as possible to keep it fairly constant impedance wise as well as minimizing loss.
As mentioned in a previous post, Motorola makes a fairly low cost ($20 range wholesale) VHF/UHF reed relay that they use in MICOR mobiles and bases as well as mocom 70 types. They are also easily repaired by removing the plastic solenoid square coil held in place with only a clip and prying the cast relay halves apart with a screwdriver. Some have a pop rivet through the middle that should be drilled out with a 1/8" drill bit first. There are 2 SPST reed relays inside, usually only one will be bad and either can be replaced with reed relays liberated from Radio Shack-style 5-12VDC reed relays. Dead Motorola relays like this used to be quite common at 2-way radio repair shops, if you have some locally try to see if you can make a deal for them to give/sell them cheap to you or save you a few in the future.
Hope this helps.

From: Jim Devenport <jdevenport@lanl.gov>
Message-ID: <4cffg1$bt6@newshost.lanl.gov>
Source record: 108466

HB gear is next to worthless resale-wise because it IS homebrew. There is no factory to contact regarding parts, design, schematics, or service information. I'm not trying to belittle homebrew gear, I'm a very avid homebrewer myself but facts are facts. Buying a hb circuit for the parts is a bad deal too since it is so labor intensive to try to salvage out parts.
About the only exception to this might be well made RF amplifiers which use common designs as well as universally available parts (usually).
Thus, my advice would be for you to hang on to your homebrew projects and show them to your grandkids or something or just drag them out and sigh over them in later years. Don't even salvage them for new projects. You will doubtless someday wish you still had those projects around. I sure wish I had followed this advice for so many of my projects of years ago that were then (and would be still) useless to most would-be buyers but priceless to the original builder or his family.

I couldn't believe I had this issue of 73 right in a small pile
at my fingertips. Your description of the problem plus a
perusal of the schematic makes me suspect some "squirrelies".
I note the COS input line is bypassed with C3, a .22 uf
capacitor. Is this in place and is it close to U4? If it is,
I recommend the following:
-Try installing .1 or .2 uf capacitors physically close to pins
4&5 of U3, pins 9 and 10 of U3, and pin 27 of U1.
-I don't see it in the circuit but all your IC's, especially
the logics (U3 and U4) should have the VCC pins bypassed with a
1 to 1 uf or so electrolytic mounted as close to the IC's as
possible and with as short a connection to circuit ground or
the IC ground as possible. I'd suggest this as your first
priority.
-You may also be experiencing RFI from your attached
transceiver. It probably should be mounted in a good rf-proof
box with incoming and outgoing wiring bypassed and/or choked
with ferrite shells and other RFI reducing techniques.
Good luck with the project. Hope some of this helps!

I have recently aquired an Eddystone EC-10 SW radio.
It doesn't work. Well actually it does but only for a few seconds
and only on the AM band. I've hooked it up to a good dipole
and looked at the power connections. It has a hum and little else.
I'd like to get this radio working but do not want to
spend mucho cash. Is there someone in the Toronto area that I
could take it to? Any ideas?
Please e-mail. Thanks.

91. Question: RF Speech Processing

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-05 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <820873939.12121@pinetree.microserve.com>
Source record: 108325

Rf speech processors normally use the SSB signal already present inside a transmitter. They clip this signal, then filter it with a second IF filter. In a 9 MHz IF, the harmonics generated by the clipping process fall around 18 MHz, 27 MHz etc., so they're easily removed by the second filter. I'm beginning to wonder if this is really necessary though, particularly if the processor is an outboard accessory.

For example, say the outboard unit used a 6 MHz carrier oscillator, fed to a balanced modulator, in order to produce a 6 MHz double sideband signal. If that signal was clipped, won't the harmonics fall on 12 MHz and above? If so, the clipped signal could be filtered with an L/C low-pass filter, then converted back to baseband (audio) using a product detector and the same 6 MHz oscillator. This would eliminate the cost of two expensive filters.

I've never seen this done, so maybe I'm overlooking something. Anyone know of a reason it won't work?

73,
Jack WB3U

I don't know if this is helpful but FWIW:

I have an FT757 (not GXII) and I installed a Fox-Tango narrow
CW filter in it. I also modified it so I could select this filter
while in SSB mode so I could use it for RTTY use. The latter mod
was simply a matter of deciphering the inscrutable Japanese logic
circuitry that controls the switching diodes for the filters and
connecting a toggle switch in the right place. I ran the wires for
the toggle switch out a hole in the rear panel. As far as the
Fox Tango filter (vastly superior to the stock one), I had to add
extra IF gain to make it useful. Actually, the radio is low in
IF gain in general so I added a second IF gain stage that is always
in place, in addition to the one just for the CW filter. It was
like a completely different radio after these mods.

94. Accurate Clock for Digital Circuits

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-05 00:00:00 UTC
From: CARDS User <mhr@aol.com>
Message-ID: <4cjesa$j4s@linus.mitre.org>
Source record: 108328

I am looking for a very accuarte clock (10 to 20 Mhz) to drive digital
circuits. The accuarcy should be roughly +/- 5 ppm at room temperatures.
If possible the circuit should be buildable with common electronic parts.
Please let me know if anyone has knowledge of an appropriate design.

Thanks to all in advance.

Mark R.

95. Re: Ham Gods: interesting questions on the nature of Hetrodyning/Spectrum Analyser guts

Newsgroup: rec.radio.amateur.homebrew

>Things I know:
>
> * We need to use hetrodyning for the same reasons as
>radios

A spectrum analyzer *is* a radio receiver, just one that tunes itself.

> * We may need to have multiple mixer 'channels' to
>deal with the enormous frequency range,
> as varactor-tuned VCOs have limited range

No. You don't want to do it this way for a number of reasons. If
you use discrete channels, you're going to have a devil of a time
gain leveling and sweep matching at the step edges. The standard
method is to use a pair of microwave oscillators in the 2.3 to 3.3
GHz range. You can VCO them in a dual loop so that the resulting
difference frequency span covers DC to 1 GHz in a single sweep.
Normally, both oscillators will be VCOs, with one doing coarse
sweep and the other doing a fine span for when you want to look
at a particular frequency range closely.

That method would be the way to go for a signal generator over
the range, or as LO for a low first IF, but you really don't want
to use a low first IF because of image problems. Better would be
to locate the first IF at 1.2 GHz, so you want your microwave
VCOs to be 3.2 GHz (fine) and 4.4 to 5.4 GHz (coarse) respectively
so that their difference will be 1.2 to 2.2 GHz, and the difference
of that output with your desired signal span will fall on the 1.2 GHz
IF frequency. Then all you need is a 1 GHz low pass filter on the
front of your analyzer to eliminate possible images.

> * We can use multiple IF stages, subsequent ones
>'tuning in the previous stage's bandwidth' with
>decreasing IF filter bandwidth as we go

Again, you're going to have a devil of a time gain matching this
cascade. You need accurate signal amplitude values across the entire
span if the spectrum analyzer output is to be of any value. What
you really want is a single mixer capable of working across the
entire range, and follow that by a fixed set of IF amps with a
calibrated response. That's much harder to achieve if you have
sweepers inside of sweepers, not to mention all the extra spurious
signals that would imply.

> * There exists nice cheap mixers like the NE602 and
>the NE600

There certainly are, but they're *crap* for spectrum analyzer
use. You need a high dynamic range (at least 100 db), and the
best way to get that is with a DBM.

> * There exists nice cheap 10.7Mhz ceramic filters with
>50kHz bandwidth (hurrah)
> * There exists nice cheap 455kHz 'IF Can' filters with
>4kHz bandwidth (hurrah)
> * The selected IF (which depends on desired bandwidth)
>goes to a log amp and a detector,
> followed by an A-D convertor in our case

You need image protection, and a 10.7 MHz first IF isn't
going to give you that over this range.

>Top three things I don't know and would like pointers

>interest? (is it 'cos the output of the mixer is
>AC-coupled internal to the mixer? :( ) I really really
>_really_ wish I could do this, because then I end up
>with a tracking generator for free.

Ok. The products coming out of a mixer are, F1, F2, F1+F2,
and F1-F2. The post mixer filter has to select *one* of them
to feed on to the IF chain. The easiest way to do that is to
make sure F2 and F1+F2 are well above the range of interest
for F1 (the signal), and that F1 is well below F1-F2. (Note
that F1-F2 will be a negative number in this mixing scheme.
That's Ok, all it means is that there will be a phase reversal
in the product and that the VCO will tune backward from what
you'd naively expect, IE the sidebands will be flipped so that
upper sideband signals will appear as lower sideband signals
and vice versa. This is a trivial problem to handle at the
detector.)

Now, why don't you want to do a DC receiver? Well, several reasons.
First, with the VCO on the same frequency as the desired signal,
IE F1=F2, the output of the mixer will be a DC level representing

the difference in *phase* of the two signals. If the two signals are of the same phase, output will be zero, if they are 180 degrees out of phase, output will be maximum. In between, the DC level will be proportional to the phase difference (with sign reversals for quadrant changes). This isn't usually the information you want to display. Now if you could maintain the LO at a fixed phase offset from the signal, the DC level would be proportional to the relative amplitudes of the two, so you'd get useful amplitude information for the display, but this is an unlikely situation. Normally, you'll be scanning the span with an LO of arbitrary phase and mixing with signals of totally unknown phase. That means all you get out of the mixer is a varying beat that's proportional more to varying phase than amplitude variation. This incidental FM is *error* as far as the spectrum measurement is concerned. We need the two frequencies to be separated far enough that this FM error falls outside the bandwidth of the post mixer filter, IE the product needs to be far away from DC.

Now you can't use a very brute DC filter either because that will limit possible sweep speed. If we say 1/T is the sweep timebase, then T can't be smaller than the settling time of the filter, IE if the settling time of the filter is 1 second, you can't sweep faster than 1 Hz/sec or the amplitude value you get out of the filter will be incorrect. This holds true at any IF, of course, and is only dependent on the bandwidth of the filter.

But the most damning reason why you don't want a DC receiver is that the opposite sideband will *alias* into the passband, IE any signal below carrier frequency will have the same difference signal as a signal the same amount above the carrier frequency. Since the products will appear on the *same* frequency at the mixer output, though phase reversed due to one of them being of a positive sign while the other will be of a negative sign as explained above, you can't separate them with a post mixer filter.

This is image reception, and should be considered a *major* source of error. The only way to avoid this is to bandlimit the input signals so that the image frequency can't pass to the mixer. That's why you want to do up conversion for the first IF. A simple low pass filter will protect from images across the entire frequency span of interest. If you use a low IF, and DC is an extreme example, you'll need *tracking* image filters in the front end. This is a *huge* headache you seriously want to avoid. With a DC receiver, this tracking filter has to be *extremely* sharp, in the limit case requiring a shoulder of infinite attenuation zero Hertz from the desired signal. That's physically impossible.

Now there is a way to use quadrature detection and phasing to remove the image, but I'm not sure you want to do this as it will be tricky over such a large span to maintain accurate quadrature.

Gary

101. SIMPLE SIMPLEX REPEATER.....HELP

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-05 00:00:00 UTC
From: tcmedlin@cris.com
Message-ID: <4ckdsh$pjc@spectator.cris.com>
Source record: 108335
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

I recently built the simple simplex repeater as described in 73 Amateur Radio Today, Nov 1995 issue. I have a bug and need help with ideas which may correct the problem. this simplex repeater is built around the ISD1000A voice record/playback IC that is available at radio shack. It has a max recording/playback time of 20 seconds. there are only 2 other simple flip-flops and a few other parts. This repeater should receive any transmission up to 20 sec, then rebroadcast that. It does that and the audio sounds good. Now here is the problem: if any received signal comes in for about one-half second or less, it then keys up the transmitter for a full 20 seconds before it will send the EOM end of message reset. this is not good because a short static burst or quick keying of the mike will lock it up for 20 sec. It functions normally of any signal over 1/2 second and up to 20 seconds. I dont think it is RF because I can manually key it up by manuall changing the voltage on the COS line and it still hangs up for 20 seconds. Does anyone have any ideas? Please email me if you can help.
thanks,
Tom, WA5KUB

Oh, ouch, I hadn't noticed that no board template was available from
the ARRL. That's normal for this type of article. Though usually boards
are offered too, either by the author or FAR Circuits. I don't like to
make PC boards, and usually order the board set for this sort of thing.
The author is trying to profit from chip, board, and kit sales (which is
fine). I haven't priced out the analog parts, but I expect there's a
moderate profit designed into them too in this case. I will say that
the author's prices look quite *fair*. This isn't a ripoff, but it is
a kit *product*, and as such really belonged under the heading of
product review.

I don't mind that QST printed this, but I think that the way they
represented it is misleading at best. I'd much have preferred that
this kit be subjected to the regular review process, complete with
lab test results. As a *product*, I find this autotuner moderately
interesting (and may order the kit after all). As a construction article,
however, I'm completely turned off by the withholding of vital information
about the *auto* part of the tuner, and now by the lack of an etching
template (even though I'd have bought the board, it's the principle of
the thing that bothers me).

Upon reflection, I frankly don't fault the author at all. I think that
it is the editors of QST who have committed a serious error of judgement
here, and who have authorized payment of League funds for the privilege
of printing what amounts to an *advertisement*. That's not the way it's
supposed to work. The company is supposed to pay QST for carrying its
ads. (I'm assuming QST paid the regular feature article rate for this ad.
If they didn't pay, then I'm only upset by them misleading us that this
is a real construction article rather than what amounts to a reprint of
a kit assembly manual.)

Ok, I'm going to take a stab at this. The first number is the
working voltage of the part, IE it's guaranteed not to conduct
below this voltage (130 volts). This is *not* the clamp voltage,
which may be 50% or so higher.

The second number is the energy rating in joules. This is how
much surge the part can handle without damage. I don't know
what the ABD letters mean, but will speculate that it may have
something to do with packaging.

I only want to make a small comment about the tuner and LDG unrelated to the issue of the ethics of the source code issue.

I ordered a tuner today. They have had such a rash of orders that they are sold out, and are struggling to restock. They have in the works an enclosure for the tuner that is smaller than the one shown in the article. It will be available in 6 weeks or so. They are also working on other projects, like a 1.5kw version of the tuner, and a voter for repeaters. Look for them to show up again in QST!

Hey, don't laugh, I toured the ETO factory (where they build Alpha
amps) and they do a lot of commercial stuff, they were building a 15kw
thing, looked like an amp/oscillator. They said it was an rf
generator to be used in a brewery for some sort of process similar to
pasteurization! Maybe this guy isn't in the wrong place after all...
Just too many cool 807's!

-
-Charles Mott

If you are worried about someone on their scanner listening in then
there isn't a problem. All they will hear is a sound like a high speed
modem. Your phone might also be spread-spectrum. If this is the
case then anyone would be hard-pressed to lock in on your signal.
As far as RF modulation, it is probably FM with 5kHz deviation.
The digital sampling is sent in a packet form, short
sections of encoded data with CRC error checking/correction.
The handset and base "lock" onto each other with a specific "code"
each time the handset is hung on the base and removed. This prevents
someone, your neighbor for instance, from accidentally using
your phone line with his ATT 9100 phone. This code changes each
time the handset is placed on the base. This "code" is a 16 bit data
word so there are 65536 combinations. The base will (should) ignore
any handset that doesn't have the right code in the digital data stream.
There is probably no encryption of the data. Since your phone and
base are communicating back and forth with a digital signal it would
be very unlikely that someone, even with the same model phone, would
be able to tap into your conversation since the bogus handset would
not be able to "lock" onto the data stream because the base would
either ignore it (not the original caller) or would cause your handset
to change channels because of interference from the bogus handset.
Now I suppose someone could build a receiver that would decode the
data stream in a "listen only" mode. They would have to know the exact
encoding scheme that ATT used for that model phone.

I hope this helps.

I foolishly posted several opinions on this subject over on qrp-l (or was it boat anchors?) just before the holidays. I had only scanned the article with the Christmas rush coming.

Many of the posts criticizing the authors and QST have lamented not being able to take the article and produce a project ranging from totally built from scrounged parts to bought the kit from the authors and put it together. I find that this article allows exactly this range!

I finally read the article carefully yesterday and found that, to the credit of the authors, the algorithm for setting the tuning is quite clearly described in the text in very general terms. I wish that QST had let them put in the flow chart (yech! We professional software types haven't used those in years) or other description of the algorithm to more precisely describe what is going on, but the prose is sufficient to do the job.

I found that what a few others suggested is quite possible. There is enough information to use another processor or a PC to do the job. An old XT class machine that is otherwise only useful as a door stop would work quite well. You only need 16 DC control lines to run the relays so you could easily do it from the parallel port of any PC with just a few latches and decode circuitry. Then you need some sort of A/D converter to do the VSWR data collection.

The board that is available could easily be modified to bring out the I/O lines for use with another controller if you don't want to roll your own.

Gee. All that bandwidth!

I guess that I missed the start of this thread, but I've seen the article and like many of you, I was disappointed that the source code was hidden. It actually doesn't look like it would be all that difficult to duplicate the software, from the description in the article, I got the impression that the software varies the inductor for closest match and then varies the cap over all the combinations.

In any case, I have to agree with the idea that it should have been called a product review instead of construction - and QST is doing this far too often. It isn't just software. A few months ago they published an article for an ATV transmitter and receiver (don't remember the exact frequency band) but the pcb pattern was not available for one of the components. Too bad you say, well with stripline components on the board it would be difficult to build without this additional information.

>73, Harry, W3IIT

I don't know what my position is on this thread; I can see it from both sides.
I can tell you a personal story, however, which in my mind answers the
profit question.

I wrote and had published in the September 1979 issue of Ham Radio Magazine an
article titled "Split-band Speach Processor". I was pleased to have it be the
lead article and be featured on the cover. The article ran eight pages and I
was paid $350. On a time and materials basis, I probably made well under a
dollar an hour. The article included complete schematics, PC board artwork and
parts placement drawings as well as design equations. I paid a friend $100 to
lay out the boards and tape the artwork. This was in the days before word
processors and auto-routers BTW. I offered no kits or PC boards.

Shortly after publication, I began receiving requests for PC boards and I was
forced to reply that I did not have a supply. I casually mentioned this to
another friend who allowed that he would put up the funds to have some made
and we could sell them and split the profit(?). So off we went and ordered 100
sets of boards at a cost of a shade over $700.

No sooner having done this, and before taking delivery, I received a board in
the mail from Circuit Board Specialists, along with a letter informing me that
they would be selling boards for my project. I also noted that the boards were
Hi-Fi; they even included the hr logo and MY call sign. Seeing our $700
suddenly go down the tube, I placed a call to Jim Fisk, Editor of hr. I
naively thought that maybe he would use Copyright to prevent further
production. He basically said he didn't care and "Oh, by the way, there will
be a kit for your processor introduced shortly." What he didn't mention was
that it would be introduced by Radiokit, his new company. Ethics. He did
suggest that I run a classified ad in hr; which I did.

We ultimately sold the 100 boards and another hundred too. I also sold, at
cost, a Plessey IC that was readily available locally, but nowhere else in

the world. We got $12 for the boards that cost a bit over seven. After figuring the time spent addressing envelopes, answering letters, etc., this was a loosing proposition too.

Was it rewarding otherwise? You bet! I got letters and orders literaly from around the world. I learned how things are delivered into some foreign countries so the post office worker doesn't get them. I made some friends. One Australian club made it a club project, over ten years later. I got some deserved criticism, which I might add was dutifully published in hr along with my response. I got some glowing testimonials. I even got to answer questions from folks that bought from Radiokit. I hope I added a little something to the hobby. All in all, it was a great experience. Profitable monetarily? No way. Would I do it again? I dunno.

I have some other article ideas. Would QST publish them? Probably not. If they did, would I try to make a buck? No. Do I have a problem with those that do? Ethically, yes. Pragmatically, no.

End of story, thanks for listening.

Regards, Wes -- N7WS

114. Bi-Directional Amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-05 00:00:00 UTC
From: Jack Mott <jackm@pmafire.inel.gov>
Message-ID: <Pine.HPP.3.91.960105212912.12361C-100000@pmafire.inel.gov>
Source record: 108348

I have a question of the technical experts in this group, although the subbject matter is slightly off-topic for this newsgroup. I have heard that cable television systems will need bi-directional amplifiers in order to support high-speed two-way communications by cable modems. Is this correct? Also, how would one design a bi-directional amplifier over a 50-800 MHz frequency range (my guess as to what the cable spectrum is)?

At higher microwave frequencies, I would design a bi-directional amplifier using two conventional amplifiers tied together with ferromagnetic circulators. However, this design approach really does not work at lower frequencies (have you ever heard of a circulator covering 50 to 800 MHz?).

If you post a response, please also send e-mail.

The ATT 9100 uses wideband FM, modulated with the CVSD data produced
by a Motorola MC3418. I suppose someone could build a receiver
or tweak another 9100 to eavesdrop, but, as far as I can tell, this
is impractical enough to be of little concern.

Certainly it is much more secure than a conventional analog FM
phone, and even much more secure than a frequency-inversion
scrambled phone. It isn't encrypted, but I would say it is
essentially secure. I'm not a security expert, though ;-)

Marcos,
Have you considered building a simple modem and doing the rest in
software like the "Poor Man's Packet" or Baycom? I know this is a
homebrewers forum, but building a whole tnc from scratch is more than
I want to tackle. The kits weren't too bad.
Good Luck,
Kerry

Does anyone have a suggestion on where to obtain the Service Manual for an H-P 8620C. I find that after lying unused for 6 months mine is now stone dead except for the illuminated power switch. Even the fan is off. Are there any other fuses apart from the line fuse near the IEC connector or will I need the schematic of the PSU?

Also, has anyone married an 8620C (eg with 86290B) to a Tek 7L18?

There is an automatic shutdown circuit in the 8620A/C that puts the
unit in the state you describe if the fan does not start or fails
for some reason. I had an old fan with bad bearings that would not
start and, as a result, caused the instrument to shut down after
a second or two. This might be your problem.

There seem to be more mainframes around than working plug-ins for them.
I have found it convenient to buy a junker for parts to keep my good one
going.

Sorry, I have no manual for mine either.

>
> * We may need to have multiple mixer 'channels' to
>deal with the enormous frequency range,
> as varactor-tuned VCOs have limited range

Not if you use an up-converting receiver whose 1st IF is above your desired band. For example, I've designed a number of 50 - 750 MHz receivers using a 1st IF of 905 MHz. Why 905? It's in the 902 - 928 MHz wireless band where many, many good & cheap & small filters are available. There is another wireless band in the 2400 MHz region. You'll still have to get down to a low 2nd IF, but the high 1st resolves a host of problems such as images, VCO tuning ranges, etc. Of course, your VCO must be locked in a synthesizer loop. Check with Motorola and Trans-Tech for the filters. There are many others.

> * If I feed the same frequency sine wave to the RF and
>LO sides of a mixer, I know I get double the frequency
>(ie, the second harmonic). But the rules of mixing

>AC-coupled internal to the mixer? :( ) I really really
>_really_ wish I could do this, because then I end up
>with a tracking generator for free.

What you need is a quadrature mixer, where you convert the input signal using a sine/cosine LO, otherwise you learn about how a mixer acts as a phase detector. Use the quadrature outputs as so -
|Vs| = sqrt(Vr^2 + Vi^2) <Vs = atan(Vi/Vr)
where Vr = cosine mixer output (real), Vi = sine mixer output (imag)

The neatest thing to do here is to digitize the quadrature mixer outputs and use DSP. That will require gain, offset compensation, ad infinitum.

> * My evil, cunning plan for generating DC-1280MHz via

>frequency 'Mecca' sounds like it should be more
>accurate.

You need one of the prescaler chips used in synthesizers that are available well into the GHz range and will work down to -20 to -30 dBm input levels. I've used parts from Motorola, California Eastern Labs, and Philips. Again, there are many others. You can get /2 , /4, etc, plus odd numbers from the dual-modulus types. You'll need these for a synthesizer anyway, unless you use one of the modern synthesizer chips which have them built in, like the National LMX23xx series - up to 2 GHz inputs.

Because of illegal CBers, the FCC required that CB equipment be very difficult to modify for out of band operation. New CB synthesiser chips were designed to implement the new regulations, and so on. This is not to say CB to ham conversions can't be done, and I've seen advertisements offering kits and info on how to accomplish it. I think most the kits involve adding an extra mixer and oscillator board. Look in the back of electronic and CB magazines for info on who sells these kits and plans.

Ditto for the circuit board artwork. Even though I might have been tempted to purchase the pre-programmed chip (I don't have a programmer for that particular device) I certainly wouldn't pay $35 U.S. for the board when I can etch my own. I actually DO enjoy etching my own boards, but not designing the artwork.
It seems to me that the author is definitely trying to make a few bucks by witholding the artwork/source code.

>So, when I saw the article, the first thing I looked for was the source code.
>When I saw that it wasn't available, I was no longer interested.

I reread the article carefully last night. From the author's description,
the algorithm *is* just a brute force search. First the L is stepped for
lowest VSWR, then C is stepped for a lower VSWR. When the VSWR falls
below 1.5:1, the tuner calls it a match and quits. If that search fails,
the C is switched to the other side of the L, changing the order of the
L network, and the brute force search of C is repeated.

That seems horribly crude, and only works at all because the L network
only has one possible match combination. That procedure wouldn't work
with a T or pi tuner, but it does eliminate the need for vector phase
measurement. The assumption seems to be that as long as the VSWR is
below 1.5:1 the no-tune transceiver will be happy so that's "good enough".

I too was disappointed by the lack of source code, or at least a commented
pseudo-code explaining the algorithm. But now that I've figured out that
this is just a brute force system, I'm not so concerned. I'm sure most of
us could program something better.

More interesting now would be a circuit that would yield both vector
magnitude and phase for the uP to work with. Then we could optimize
the network quickly for *best* match. Anyone have any candidate
circuits that could be retrofitted to the design?

Well said, Mike. You've described the problem with this article in
a nutshell. I'd suggest that the majority of people who are interested
in construction articles never exactly duplicate the project as described.
Instead they take *ideas* from the project to incorporate into their own
projects, or simply read the article to find out how something works,
IE purely for educational value. The article as published serves neither
purpose well. There's nothing novel or particularly instructive about
a switched L network. All of the novel and appealing features of this
article revolve around the *auto* part of the autotuner. And that's been
kept a secret black box.

I haven't worked through the math, but I think the problem is
with clipping DSB. If the clipping isn't perfectly symmetric,
IE both positive and negative frequency, some horrible *in-band*
distortion products are likely to be produced.

>have the money to by that one part that could only be bought from that
>special place, who ever or were ever it might be.

Well, of course you still can. But getting on the air with almost nothing
at all leaves you with almost nothing to show for it. That is to say, your
capabilities are comensurately limited. It's always been true that if you
wanted to operate at the upper levels, you had to commit greater resources.
In the 50s and early 60s that meant many vacuum tubes, today it only means
a handful of ICs. But it still isn't almost nothing.

High power tubes, and their power supplies, were a challenge to the
builder of yore. Today, most things can run off a 12 volt source, IE
a car battery. That's much better for the 12 year old since he's less
likely to kill himself, and it's usually *cheaper* too. ICs (cheap
ICs) allow today's builder to do things that would have been thought
beyond the reach of an amateur builder of the 1950s. All today's
builder needs is the *information* about these ICs, how they work and

how to apply them. A project which treats them as magic boxes is doing
the reader a disservice. (Sometimes a designer *can* treat such parts
as black boxes, but he needs to understand how and why he can do so,
IE he needs the transfer function of the part. That's the algorithm
of the tuner in this case, and that's being withheld.)

>Have you ever longed to build something electronic at the age of 12 or
>so, and had no money, but the author gave you a way to do in in the
>article, like the code for the chip, or the turns count and size of the
>coil.

Well, lets be fair here. What the author is charging for the programmed
chip is very close to what it would cost you to buy a blank chip and
program it. Having the source code wouldn't measurably reduce the cost
of this project. But it would increase the *value* of the project as an
educational experience. What might reduce the cost of the project would
be the ARRL furnishing an etching template, as they do with most QST
construction projects. While $35 for an etched board isn't overwhelming,
it is a significant cost factor. Of course you could point to point wire
it and save that $35. I think looking at cost in this article is a strawman,
however. The cost for the programmed chip, the cost for the full kit, aren't
out of line at all for an *auto* tuner. Where I fault the article is that
it gives essentially *zero* information about the *auto* part of the tuner
while concentrating on the assembly of the switched L network. There's nothing
very interesting or novel about that. Any number of tuner articles exist.
What makes this one interesting is the *auto* feature, and that has been
totally hidden from the reader.

>I believe,(This is only me talking.) and I am a member of ARRL and you
>have published 2 very popular articles I wrote, at least my fan mail said

>THE LOVE OF IT, but has gone into business, targeting those people who
>would buy more magazines, (Your on the news stand now.) books, and other
>offers the ARRL has, and has geared it QST publication toward them.

I think you're being unfair here. The ARRL has, for essentially the
first time, tried to get serious about spreading the word about amateur
radio outside of the insular group of insiders (mostly greying) who've
made up the service these last couple of decades. School radio clubs
are dead (thanks mainly to the Incentive Licensing debacle, but that's
another topic), and reaching out and recruiting new blood now depends
on other means. The ARRL has put QST on the newsstand to try to reach
some of that new blood, and expose them to what amateur radio is about.
I think that's a very positive step. And the books and programs the
ARRL offers are about the best that they've ever been for the task of
educating amateurs and potential amateurs about the service and its
technical aspects. I congratulate them for these expanded publications.
They are filling a void no one else wishes to address.

>Who are those people, (Me talking again.) thay are people who never grew
>up in ham radio scrounging a part or a who rig full of parts to get on
>the air, and if the truth be known, computer have the interest of the

>young people, not ham radio. I can talk any were in the world on internet
>who needs a radio.

The people being targeted are indeed young and computer literate. Would you have them winding spark coils in their basements? The technology and focus of amateur radio have to move past that era in order to be relevant to a modern society used to technological marvels. It's true that "working the world" just to collect postal cards is no longer a challenge to most of today's technologically literate population. As a radio *game* it still holds some interest for a few, but it no longer is technologically relevant. And it has offered little actual utility for decades. Instead, we see wireless networking as a hot topic still on the cutting edge, ALE techniques looming on the horizon, and spread spectrum as a coming thing. And we also see technical curiosity as a prime motivator (as it always has been). People want to understand the technology behind the magic boxes. That's where this autotuner article fails. It *hides* the relevant technology in a black box.

>Those are the people targeted by QST. We all see the QRP articales, about
>the only rig that can be built any more, if one can find a variable
>capacitor. Have you even seen a dealer advertise a line of variable
>capacitors in QST or any were elce.

Rarely, but that's not a big problem since we can use electronic tuning today. Varactors, controlled either by a synthesizer or a simple pot, do our tuning (or we use DDS). I do fault QST for presenting mostly QRP CW articles based on elderly technology. Old parts have disappeared for a reason, there are better ways of accomplishing the task today. QRP CW transmitters *aren't* the only things we can build today. It's easier than ever to produce top notch projects today, thanks mainly to the uP and other high integration ICs. But we need the *information* in order to do so. QST has with this article begun to *hide* that information from the reader. That's a very bad precedent.

I'm also something of a machinist. In that world, precision work was horribly expensive to do when the precision depended solely on mechanical tolerances of the machining equipment. But today, thanks to the uP and CNC, even sloppy equipment can be programmed to do good work by using the power of the uP to *compensate* for the slop of the tooling. So instead of spending tens of thousands for a Bridgeport, we can use a cheap Tiawan mill and add CNC to it which can compensate for tooling hystersis. But an old time machinist can't benefit from that because he won't learn new technology. And newer machinists won't benefit from the technique unless there are publications out there *explaining* how the new techniques work.

>I have been in hard electronic repair
>for 35 years, and I can fix hundreds of things not made anymore, or will
>never be made again. Why, becasue it all gone to software, and QST won't
>publish it so we can use are new skills and try and program our EPROM or
>processor chip, we have to buy it, just like Popular Electronics.

Yeah, right on. It is the purpose of QST to serve primarily as an *educational* vehicle, to expose us to newer technologies and to

explain newer technology through examples called construction projects (old tech is adequately covered in references like the Handbook). That generally doesn't happen by publishing the Nth iteration of a QRP CW transmitter, or the Nth iteration of a Morse keyer, though there is a limited ability to expose us to newer parts with these projects. What we need instead are projects that fire the imagination, that pass on newer and better techniques, that do something novel or useful that we otherwise couldn't either afford or understand.

I can throttle back any commercial rig to do QRP CW, yet another QRP CW transmitter construction article doesn't offer me anything of value. A high performance HF modem, however, would offer something few would be able to obtain commercially, and serve to explain coding theory and signal design, construction, and deconstruction to the reader. Even if never built, such a construction article would serve a valuable purpose by explaining what goes on inside the magic black box.

>When is the last time we saw a 75 watt Novice rig in QST built and
>presented by the ARRL lab.

Probably sometime in the 1960s when such a rig was still relevant.

>Packet is the revolution for those with
>interest in computers. I can use computers, and repair them, thank you. I
>tried packet and sold it. My time is better spent on something that is
>real time then waiting on the postman.

It's true that early packet equipment was dismal (and by inertia still is in many cases), but this is a young technology, and better things are being developed nearly every day. For example, 56 kb RF modems have been available since 1987. We rarely see them mentioned in QST where 9600 baud seems new and hot (while it is really old and nearly passe). Megabit wireless networks are feasible today in amateur radio, but reading QST you'd never know that. Instead they offer us a Baycom style modem that struggles to do 1200 baud. That serves to perpetuate and reinforce the myth that digital is inherently low performance and difficult. In fact, systems only marginally more complex can perform *much* better.

Frustrated by network delay, and by the purely political reason it continues to exist (building networks is 99% politics 1% technical), amateur designers have turned their attention to the challenges of HF digital where much of the politics can be bypassed by direct realtime connections. PACTOR II and Clover II offer us performance exceeding that of OOK Morse *today*, and better systems are possible. Thanks to inexpensive DSP development platforms, like the Analog Devices EZkit, and some sound cards using the PSA chipset, we can participate as homebrewers in this exciting field. But you'd never know that from reading QST feature articles.

Reading QST, you'd think OOK Morse QRP was state of the art. Reading QST, you'd think uPs are magic black boxes you have to buy from someone already preprogrammed, even when the function is as simple as an antenna

tuning algorithm. In fact, reading QST you might get the impression that stringing a wire antenna was a major technological accomplishment.

>I, and people like me, are no longer the interest of the ARRL, or QST. I
>love ham radio. It has gotten me good jobs from the skills it has given
>me. I have talked to lots of people. Years ago thay all built something,
>today most do not even own a good soldering iron. QST know that. I, and
>the 12 and 13 year olds are no longer the target, the kit builder, and
>the buyer of new equipment is because there in no money in me and a 12
>year old. There never has been any money in me and my kind in ham radio
>because we build from parts, which there is no money in.

I think you are wrong. QST isn't after your money, but it is trying to cater to what it perceives as its readership. That's understandable for any publication. If people aren't interested in reading what is presented, the magazine accomplishes nothing. Where I think QST fails is in the role of leader. Most of us aren't aware of better ways until someone shows them to us. Most of us can't do more than solder together a kit unless someone explains how the circuitry works on a level where we can design our own. QST fails by underestimating the intelligence of their readers and catering to the LCD instead of striving to inspire the masses to excellence.

Instead of regurgitating for the Nth time that QRP CW transmitter, they should point beginners to the appropriate reference works where such things are adequately covered (unless something new is introduced in the project, such as DDS). In QST, they should be introducing the readership to newer and more relevant projects and ideas. They should serve to inspire the reader to try something newer or better than what he has done in the past. That could be an autotuner, it could be something like a small tuned HF loop (which while simple, embodies subtle principles and techniques not generally well understood). It could be a homebrew HF modem using DSP (with algorithms adequately explained), or it could be a simple quadrature exciter or receiver (such as the excellent Rick Campbell T2 and R2, they did good there). But yet another carbon copy 3 transistor QRP CW rig? I could scream.

Occasionally, I think QST should tackle a *major* project, perhaps spanning multiple issues. Such a project should address state of the art in some facet of amateur radio. That was done in the past with advanced tube receivers and SSB transmitter projects. Today such things are passe, with high performance equipment available off the shelf to address that need. But advanced digital technique on HF and VHF isn't well covered, microwave projects are for the most part limited to yet another preamp, etc. A major SOTA station design project could be very educational and interesting even if few people ever built it as described. Most construction project articles are of interest mostly for what you can *learn* from them rather than for slavishly copying the project. And most construction projects only show one subsystem of a more complex station. By addressing a total station package in a series, the reader will learn how the bits and pieces fit together into a

coherent whole, and learn something about the tradeoffs required
to integrate the bits and pieces into a functional whole. That's
been sorely missing from QST.

>We are the ones that some QST articles have made fun of because we see a
>good deal in a broken radio, and can fix it, or see the value in a pile
>of junk that know one elce can recognize, and are no longer recongnized
>by QST.
>
>That is why the missing chip code to the ATU article is importent. Not
>because you can build the unit by odering the part, but because you can
>not say, on the air, I programed the chip myself from and article in QST.

Well, I certainly agree that *understanding how it works* should be the
major goal of any construction article published in QST. Without that
knowledge, you're just an assembly line worker blindly following directions
of "insert wire, solder one", which teaches you very little that you can
apply to your own projects.

I hate making up harnesses, and hate doing point to point wiring. I'll
buy a circuit board, I'll even often buy a complete kit, rather than
put up with the hassle of searching out all the parts on my own and
hand wiring it all up. But I damn sure want to know *how it works*
in detail before I build it. I want to know if it will meet my needs,
and if not how I can modify it to do so, before I build it. I don't
want it to contain black boxes labeled "Here there be magic" inside.
I'll tolerate that from a manufactured product to an extent, though
I strongly condemn Icom for failing to include schematics and theory
of operation with their IC-706, but I won't tolerate it in something
I have to build.

I don't homebrew to save money, my time is worth more than an assembly
line worker's wages. I homebrew to get some functionality I can't get
otherwise, and I homebrew to *learn* circuit design and behavior from
the example of the project presented to me. I might tolerate this auto
tuner project if I couldn't buy one off the shelf wired and tested,
but I *can*, so the only value it holds for me is the educational benefit
of learning how auto tuners work. That's being denied me here, so I
don't like it one little bit.

Note: I don't fault the author, he's just trying to make a buck. I
fault the editors of QST for paying for and publishing this advertisement
in lieu of publishing something that would *teach* the reader something.

137. Re: 900 MHz Security

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-06 00:00:00 UTC
From: TSJV87A@prodigy.com
Message-ID: <4ckoq9$tlk@usenetp1.news.prodigy.com>
Source record: 108355

Being Digital I would think that it offers some security. Since it will take time for the average listener to get equipment to decode it. The most secure is the ATT Escort that contains Spread Spectrum Modulation from what I have read. This offers another layer of security. I am sorry that I do not know a lot of specifics about these models. But if I buy a cordless for business it will be one that does Spread Spectrum Modulation techniques. It randomly transmits bits of your signal on various frequencies.

I agree with you (and others) completely. The issue here is with OUR publication QST and how we want it to be run. I think the authors are nice persons and are just taking advantage of the free advertising.
It's interesting how many have changed the subject when they reply to this position on QST and what we thought QST was about. I have gotten beat over the head with everything from "smatter...you too cheap to pay a few bucks for the three cents per hour hard work of the authors?" to "lighten up...big deal...if you don't like it don't buy it" to "there are a lot of people out there who will gain all sorts of benefit from building this kit, and if you think you're so above it go write your own code". Someone even wrote that the authors have been swamped with orders (which sounded like an endorsement of the decision to publish the article). Well, I'm not surprised. Five full pages in the magazine is a lot of coverage.
Well, none of these arguments are the issue. There is nothing practical about the real issue, and nothing needs to be solved for me. This is about the concept of a member publication of an organization run for the sake of the art. If no one is interested in the art of amateur radio to write an article with no strings attached for the sake of sharing the knowledge, then no one is interested. Period. I don't think that the editors should approach that problem by changing the rules (I know that I am assuming that I we agreed on some rules....maybe not).

142. QST Antenna Tuner Kit-First Impressions

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-06 00:00:00 UTC
From: garland@ohstpy.mps.ohio-state.edu
Message-ID: <1996Jan6.185503.8669@ohstpy>
Source record: 108360

Having started all the commotion about the QST automatic tuner article with my posting several weeks ago, I decided to buy the "kit" and take a first-hand look at the product. I haven't wired it yet, but thought I'd offer my first impressions on the unassembled components and documentation, since there seems to be a great deal of interest in the tuner. What arrived is, in fact, a full-fledged kit, with an eleven page assembly manual that includes a parts list, parts placement drawing, suggested front panel layout, and carefully drawn sketches on wiring up the toroids. A schematic is included, as is a block diagram and a front panel wiring diagram. The manual is nicely written with step-by-step instructions that fall only slightly short of Heathkit quality.

Predictably, no information is given about the software, but it is noted that future upgrades will ba available for about $10, with trade-in of the old 68HC11 chip.

The parts are packaged nicely, with the eight toroid cores comprising most of the weight. All the components are off-the-shelf pieces, that one could buy at Digikey or similar suppliers. Two SO239 connectors are also supplied.

My only quibble with the kit is the printed circuit board. The board itself is of high quality. It is double-sided, with thru-plated holes, green solder-masking, and silk-screened component outlines shown in white. My concern about the board is that the large majority of the traces seem to be extremely thin. I couldn't measure them, but I'd guess a maximum width of 10 mil, and probably less, perhaps even 6-7 mil. (all the relay control lines are wired this way.) Further, the pad sizes seem too small
relative to the holes in the pad. I'm not an expert at PCB layout, but I'd think that a pad should have a minimum of 10-15mil of metal around each hole. The majority of holes on the board have significantly less metal than this. In fact, a majority of the holes were drilled slightly off-center in the pads, so that there is no metal at all on one side of the hole!

IMHO it is regretable that the board was laid out this way, since components are quite widely spaced and significantly thicker traces could have been specified. I'm worried that the slightest flexing of the board (as might occur in mobile service) may break hairline traces. I'm also worried that pads may come loose at soldering temperatues, since there is so little metal adhering to the board. If you're thinking about buying the kit, you might want to keep these points in mind. It's a shame, really, because a great deal of care and thought went into putting the kit together.

More, when I have the kit up and running.

Source record: 108361

Hello,

I want to program a OTP (one time programmable) Motorola
microcontroller MC68HC705C8 using a circuit given in the
Motorola manual which transfers data from a 2764 eprom into
the controller.

The question is the data book is unclear about the programming
voltage (Vpp). At one place it says 16 V maximum but it never gives
a typical or 'correct' voltage? 12 Vdc? Is 13.8 Vdc ok?

Thanks for any help.

Ron, w8gus.

Source record: 108363

A friend of mine used to design phase locked oscillators for communications satellites. These oscillators operated in the 400 or 500 MHz range and used a very high Q cavity.

The power supply to the oscillator that they used was made by using a couple of series zener diodes with a fet as the "load resistor". This provided the reference voltage to a current source that provided the power to the oscillator. The key was the zener diodes. The ones they used have very sharp knees and were made by TRW at the time. I'm not aware of TRW still being in the business but other companies provide sharp knee zeners that may provide the characteristics needed. My friend said that the zeners had a very steep slope of voltage vs current which resulted in a very stable reference source.

There are other parameters to consider obviously since at least one design of a noise bridge back in the early 70's used a zener as the noise source.

Tom, could you elaborate on this? I was surprised by your statement, given the 8 dB or so improvement possible with RF processing. Of course, I can see how splitting the audio spectrum to enable effective filtering of harmonics could be as effective, but not more so. BTW, I've missed the articles on the split band approach due to two absences from the hobby. If the explanation is complex, I'll try to round them up.

>But I have no feel for the level.

I thought about that too, but I don't see how the distortion products could fall in the RF passband. For instance, let's say the balanced modulator is operating at 6 MHz and that it's modulated with a 1 KHz tone. The output will be two carriers (DSB), one at 5,999 KHz and the other at 6,001 KHz. What combination of those two carriers produces a distortion product that falls near the two fundamentals?

Incidentally, there was an RF processor showcased in the October '95 issue of CQ. It's made in by GFS Electronics in Australia and it's supplied on a small PC board, intended for internal mounting. According to the short description, it connects in series with the microphone audio. Looking at the picture, there does not appear to be a crystal filter on the board. Anyone know anything about this unit?

Hi Jim,

The Vomax was a split band audio processor which is superior to RF
processing. I still use a modified VOMAX with my 751A.

Wes N7WS had a nice article in some magazine years ago, it was good enough
to be copied (hopefully he was compensated) and sold by two other
companies.

I see Gary's point. If an unfiltered DSB signal is clipped and re-mixed to
audio, it will have extra unnecessary distortion products in the output.
But I have no feel for the level.

Splitting into sub-bands, processing, filtering, and re-combining is
always the best approach. As long as correct phase between signal channels
is maintained. Hopefully Wes will show up, since he designed a system.

Guess that I missed the initial posting, but according to a somewhat old
GE MOV book, 2nd edition:

THe V130 parts are rated for 130VAC or 175VDC continuous, and clamp at
between 184 (Min) and 230V (measured with 1ma current).

The 'LA10A is rated 30Joules/peak current 4000A
The 'LA20A is rated 50joules/peak current 6000A
The 'LA20B is rated 50joules/ " " "

The difference between the 20A and the 20B seems to be that the 20B has a
somewhat better spec on clamping resistance and slightly lower clamp
volt.

My book doesn't show the other two parts, but I would guess that the LA13
is inbetween the LA10 and LA20.

If anyone would like, I could fax a copy of this page of the book to you.

There have been a handful of articles in ham publications over the years on automatic antenna tuners and most have used a standard design of a phase and magnitude indicator. This standard design is very similar to wattmeter designs that involve passing the center conductor of a transmission line thru a big toroid to sense line current, then take the dot product of it with the line voltage (easily sensed with a capacitive voltage divider). By a slight rearrangement of things you can instead get an indication of phase (capacitive or inductive) and magnitude (greater or less than z-zero). The resulting device is sort of a cross between a wattmeter and a VSWR meter, in terms of constructional characteristics.
Anyone have a non-obscure article citation that describes one of these?
A dumb old analog control circuit using one of these phase/magnitude sensors can run rings around most VSWR only circuits, even if they use a secret digital algorithm. I know of a commercial tuner that could lock up in less than 1/2 second to any matchable load, without presetting from a look up table. Didn't even have a microprocessor either. I don't understand all the excitement about the QST article. I wouldn't want the design if it was free.

From what I've read, the double sideband when clipped (hard) generates harmonics at the double freq etc which remix with the original in all the possible combinations. Unfortunately the opposite sidebands of the fundamental and the first harmonic mix and trash each other before either a: going thru the side band filter or b: being detected back to audio.

The result is no better than audio clipping.

What I fail to understand is why designers use such extreme clipping to actually make the harmonic generation worse. The b-e junction is often used for this purpose, whereas I would have thought something a bit 'slusshy' would have generated less clipping/mixing/hash?

> deal with the enormous frequency range,
> as varactor-tuned VCOs have limited range

If you put the first IF above the input range (say 1.5 GHz) then the
VCO tunning range is less than an octave (1.5 GHz - 2.5 GHz), which
can be tunned with a single VCO. However, there can be phase noise problems
with such a wide range.

> * If I feed the same frequency sine wave to the RF and
> LO sides of a mixer, I know I get double the frequency
> (ie, the second harmonic). But the rules of mixing
> seem to indicate I will also get some kind of component
> at DC, ie f+f=2f, and then f-f=0.

If your mixer really operates as a four-quadrant multiplier (such as the
Gilbert-cell at proper signal levels) you get

sin(a)*sin(b) = 0.5*(cos(a-b)-cos(a+b))

if a = b, that is same frequency and same phase, we get

sin(a)*sin(a) = 0.5*(1-cos(2a))

that is a DC term and a signal at twice the input frequency.

However, if you are using a square wave as LO or are using a switching type
mixer (such as overdriven Gilbert-cell in NE602 or a diode ring mixer
such as SBL-1), you have strong responses also at 3f, 5f, 7f etc.
This is tolerable for a ham-band-only direct conversion receiver, while
you can use band-pass filters at the RF-port, but it is definitely not a
nice thing in a spectrum analyzer without tracking input filters.

> Assuming you are not
> already choking on your beer with laughter at this
> newbie blunder, why then does one need a detector? Why
> can't I run the LO at the frequency I'm interested in,

> slug the mixer output with some brutal filter that
> suffocates anything past a few Hz and accept the result
> as reflecting the RF energy at the frequency of
> interest?

You can do this, but then you have to accept that the sensivity and/or dynamic range will be poor. In addition to the odd harmonic response problem, there are all the same problems as with direct conversion receivers. A good article is "Improving Direct Conversion Receiver Design" by Nic Hamilton, G4TXG in "Radio Communication" (published by Radio Society of Great Britain) April 1991 pp. 39-44).

Few of the problems are:

* all of the required gain (80 - 120 dB) is on a single frequency (300 Hz - 3000 Hz) after the mixer. At audio frequencies, this will cause some microphonics and hum pick-up (50/60 Hz + harmonics). In a spectrum analyzer, the frequency response should extend down to DC. 80 - 120 dB DC-gain is something to avoid ! You can get laser trimmed instrumentation amplifiers with 50 uV input offset and 0.25 uV/C temperature drift, but they are not cheap.

* The LO-signal will eventually leak into the RF-port (by direct radiation or by leakage through the mixer LO-port to RF-port and then reflected back if there are any mismatches in the input stages. In a direct conversion receiver, this will cause some adverse effects, RF-hum pick-up etc. In a spectrum analyzer, this is a more serious problem. The mixer output there is a DC-voltage proportional to the RF-port signal, which is in phase with the LO-signal. You get a DC-voltage proportional to the LO-leakage ! You could get away with this by using a harmonic mixer and drive it with f/2, but there are spurious responses on other frequencies.

* In many mixers, the noise figure deteriorates at low frequencies due to 1/f noise.

> (is it 'cos the output of the mixer is
> AC-coupled internal to the mixer? :( )

The Gilbert-cell mixer is a balanced construction, so you can get a differential voltage between the collectors. However, I have not seen any specs for the bias stability of these devices. Even if you could get a good DC-amplifier, you still need some active circuits to compensate for the mixer drift.

In an article by John C. Reed "Spectral Measurements the Hard Way", in QEX July 1995, pp. 16-20 (published by the ARRL), a spectrum measuring device is described with first IF at 25 kHz. This will overcome most of the problems caused by DC-amplification in direct conversion spectral measurement. Due to the principle of operation, it will have a response both 25 kHz below and 25 kHz above the LO frequency. This should not be a problem if you are interested only in harmonics of a signal source, but can be problematic when doing

narrow bandwidth measurements from a continuos spectrum.

For Sale:

(2) ELPAC OLV30-12 Power Supplies, 12v, 4.0A (Adj. 4v,6A.
to 28v, 1.7A.) With Remote Sensing, (Instructions/Spec. Sheet
Included)

Guaranteed Specs:

1. Line Regulation: +/- .1% Output For
+/- 10% Input Variation

2. Load Regulation: +/- .1% Output for No Load
to Rated Load

3. Ripple: .1% P-P Output For
No Load to Rated Load

4. Ambient Temperature: 0-55 degrees C

Input: 120vac or 240vac

I'm selling the (2) units together. One has been wired for
120VAC and is putting out 12V. The other unit appears to have
been worked on and the AC cord has been removed. It may or
may not work, so I'm selling it as is. $25.00 plus shipping
for both.

Also available:

Variac V10-G3/POWER SUPPLY in steel cabinet with whisper
fan and Simpson DC volt and amp. meters. Marked "General Radio"
on handwritten tag inside case. 115v. Input 10a. 50-60 ~
I checked the output with a meter and it seems to range
from 1 or 2v. to approx. 30v. Dial is calibrated from 0 to
130. It appears to be set up as a battery charger or transformer
as it has (2) heavy output leads with battery style spring
clamps. $75.00 plus shipping (heavy)

Thanks for your consideration,

Steve

Due to all the intrest in the QST antenna tunner article I have generated a list of related articles I have on file. If any one has any others not listed I'd like to hear about them and try to obtain a copy.

Electronics Dec 1951 "Automatic Impedance Matcher" by Virgil True This is a servo driven circuit that uses the Phase Magnitude detector that was standard in commerical military applications for years to come.

Qst July 1952 "A Phase Detector for RF Transmission Lines" by Robert Mezger W2BLL A description of the Phase detector with vector diagrams ect.

QST August 1952 "Automatic Tunning of the Antenna Coupler" by Walter A. Knoop. This is a stab of an Auto tunne for a link coupler for ballanced lines. Uses a phase detector and addresses the problem of the link keeping the circuit from exact reasonance. Serries capacitor in serries with the Link. Inresting reading for those of you using balanced feed.

CQ December " 1952 "The True Matcher" by Capt. R. R. Hay USN W4LW This is a description of a phase magnitude indicator.

CQ July 1953 " Additional Notes on the True Matcher." by Capt R.R. Hay Capt. USN W4LW

CQ January 1954 "Problems in Automatic Antenna Tunner Design" by Capt R.R. Hay USN W4LW.

CQ June 1954 "The Automatic Match" by Capt R.R. Hay Capt. USN W4LW. Capt Hay puts his Phase magnitude detector to work driving servos to match his system.

CQ Feb 1956 "RF Phase Sensing Unit and Impedance Magnitude Indicator" M.K. Brooks and W. Brooks

QST Dec. 1956 "Automatic Antenna Tunning for the Amateur" by Lois Hutton W0BQF. He did it right way back then.....Look Ma no Transistors.....My words not his

CQ Jan 1962 "Building and Using the Coax Phase Detector" by David Geiser Wa2ANU. Good article on building a phase detector principle.

CQ August 1962 "How The Coax Phase Detector Works" by David T. Geiser. A folowup article digging in to the theory of an earlier constructon article.

73 July 1979 "Tennamatic: An Auto-Tuning Mobile Antenna System" B.F. Brown W6TWW This isn't a tunner per say but resonants the Antenna. Is still used on the popular screwdriver types of antennas however you must move the coil to the proper band as it ignores the impedence. Great article.

QST April 1980 "A T-Network Semi-automatic Antenna Tunner" Bill Imamura JA8GW This is a VSWR only driven tunner.

QST July 1980 "The Impedance Match Indicator" by David Geiser " WA2ANU Another tutorial on the phase and Magnitude detector with a good construction article.

QST October 1982 " Mobile Antenna Matching --Automatically!" Don Johnson W6AAQ This is a re write of the July 1979 "73" article. Also both articles are in the book"40 +5 years of HF Mobileing" by Don Johnson. Published by World Radio .

CQ April 1987 "CQ Reviews the Icom AH-2 HF Mobile Antenna System" Lew McCoy W1ICP This is a review but includes the schamatic. Notice it is Phase and Impedance driven. Very similar to the current QST article. If anyone looks at this circuit I'd like thier opinion on the purpose C165-167. Is this only so they can advertise it as a pie tunner?

QST January 1996 "An Automatic Antenna Tunner: The AT-11" by Dewayne Kincaid WD8OYG This is the first digitial based tunner article I have on file. (Except for the review if the Icom AH-2) . It is also the first construction article that witholds information on the operation of the unit. It is also the first construction article that gives the project a product type name the "AT-11" Lots of firsts here and not all of them good IMHO>

>Rick Karlquist N6RK
>rkarlqu@scd.hp.com

Well I have seen several servo tuners but never seen one that could
move very far in 1/2 second. Most took several seconds to turn a
rolller inductor thru a gear head motor. However they all did use a
phase magnitude detector.

I do have to say that I have a great deal of respect for the circuit
in this article as I haven't seen anyone else publish anything better.
And a few years ago QST published a servo driven VSWR driven circuit
that was just awfull.

Also the magnitude detectors usually try and determine if the load is greater than or less than 50 ohms.

Several of the circuits in the ham publications over the years have only used phase detectors which required you to manually get in the band. The Ten a Matic for example. Other wise they will tune you to the equivalent of a 1/2 wave or any other resonant length.

A good description of the phase detector is in a couple of articles by David Geiser Wa2anu CQ Aug 1962 and then in the July 1980 QST. In the Qst article he also covers the magnitude(impedence) detector(indicator).

In another message is a list of the related articles I have if any one is intrested.

>the other at 6,001 KHz. What combination of those two carriers
>produces a distortion product that falls near the two fundamentals?

Ok, here's the problem. When you go to demodulate DSB back to audio, the output is the vector sum of *both* sidebands with the reintroduced carrier. You know what AM sounds like under selective fading, well the same thing is possible here if the clipping of the upper and lower sidebands isn't precisely symmetrical in both the amplitude and frequency domains. The latter is what's different about DSB. The sidebands are *mirror* images in the frequency domain, so the clipping also has to be mirror imaged in the frequency domain. That's not necessary with SSB.

Depending on how the clipper is implemented, there can be considerable differences induced in the phase/amplitude envelopes of one sideband and its mirror image. Those differences will show up as in-band distortion products. I don't have a feel for how great a problem this may be, but I'm sure it is a problem (it is for AM broadcast transmitters using compression), and there's no way to simply filter out these components. My gut feel is that it's important to use a carrier as high in frequency as possible for modulating and demodulating the DSB signal so that the percentage bandwidth is minimized and possible asymmetries in the frequency domain are reduced.

Another potential problem is reciprocal mixing in the demodulator. The clipped sidebands will generate a *pair* of harmonics for each audio generated product. To take the steady state example you pose, the LSB will have a harmonic at 11.998 MHz while the USB will have a harmonic at 12.002 MHz. Those two can *also* mix in the demodulator yielding a difference product of 4 kHz which will be in the output audio passband. Now that particular product is high enough to be audio filtered in the output, but consider if there is a 500 Hz

component present in the input audio, its product will fall on
2 kHz in the output, and that's in the speech band. The obvious
solution to this problem is a lowpass filter between the clipper
and the demodulator. But that lowpass filter has to be pretty
good to eliminate sensible products in the output. The lowpass
in a SSB clipper doesn't have to be quite as good since it doesn't
have to deal with paired products, IE there are only half as many
potential mixing products that can fall in the speech bandwidth
of the output with SSB *and* they are unrelated in phase, so
there's a potential for at least 6 db worse distortion products
out of a DSB clipper than a SSB clipper.

It's a rule of thumb that products more than 20 db below the
average level of an audio signal are not sensible for communications
purposes. So we need a lowpass with at least 20 db of attenuation in
the SSB case, but at least 26 db in the DSB case to reduce this in-band
distortion below sensible levels. I don't think this is a big deal, and
it rapidly gets better as the order of the harmonics increase, but it
is another disadvantage of the DSB clipper approach. And we should
remember that clipping raises the average level of the audio (that's
why we're doing it), so 8 db of compression makes our filter requirement
8 db greater too. A clean DSB clipper thus may need a filter of 34 db.

I have this crazy way of looking at things sometimes. I just said to myself, "Self, if you *wanted* to clip each sideband in this DSB signal independently, what is the likelyhood that you could do it with a simple clipping circuit?" And I answered, "Beats me :-)"

>Depending on how the clipper is implemented, there can be considerable

I think it's too late to use a low-pass after the clipper. The intermod
products can (will) be generated in the clipper. After all, it's a
highly non-linear device, perfectly suited for mixing. For example:

Two audio tones, 500 and 1000 Hz applied to the balanced mixer along with
a 6 MHz carrier. Output is 6 MHz (suppressed), 5.999, 5.9995, 6.0005 and
6.001 MHz. Assume an USB filter. Output is now 6.0005 and 6.001 MHz.
Clip the hell out of it and get 6.0005, 6.001, 12.001, 12.002, 18.0015,
18.003... Also, get (12.002-6.0005 = 6.0015) and (18.003-12.001 = 6.002)
which both fall in the passband of the following LPF and BPF. It might be
argued that if the clipping is perfectly symmetrical, there won't be a 12.001
and 12.002, but (18.0015-6.0005 = 12.001) and (18.003-6.001 = 12.002) so there
they are. The split-band approach doesn't suffer this particular problem.

One can further argue (correctly) that this example is steady state as in
two-tone testing and not much of a problem with intermittent speech. However,
steady state is certainly the easiest way to compare systems.

>But I have no feel for the level.

I posted on this before, but hadn't read Jack' s post
carefully enough to see that he was talking about a *DSB*
signal. The Comdel approach that I mentioned was an *SSB*
processor. As Gary and Tom note, there will probably be a
distortion penalty to pay. You also have to be very careful
to have the clipping occur only in the clipping circuit, not
elsewhere where it is uncontrolled.

>Splitting into sub-bands, processing, filtering, and re-combining is
>always the best approach. As long as correct phase between signal channels
>is maintained. Hopefully Wes will show up, since he designed a system.

I'm here!

I agree, although, you must be very careful to minimize
lower frequency distortion ahead of the first band-splitting
filters. Distortion products are harmonics and if the input

signal contains them, they can pass into one of the higher frequency filters, where if they are small enough, they remain unclipped. Meanwhile, the higher amplitude, lower frequency signal is clipped, ie. its amplitude is reduced. Coming out of the second set of filters, the two signals are combined and... oops; compared to the fundamental, the harmonic amplitude has actually increased. The distortion has increased by the clipping ratio; exactly what we don't want. Of course, we usually analyze these things under steady-state conditions. With speech, this is much less of a problem.

I wonder if anyone looked at the voltage a MOV requires before the resistance really drops a lot, and compared that to the current the device you are protecting would be drawing at the same voltage. It's been a while since I looked at them, but when I did they almost were worthless for power line protection.

Well Stated !

In fact all the ARRL rigs are now big comerical units from what I have heard. More like a coastal station for ships at sea. The ARRL has all the tools to do board design and maybe even fab. Why isn't this offered as a service to the members for projects such as this tunner? Why aren't the lab services in general more available to the membership or are they and I'm just unaware of it?

What was the last Yaesu, Kenwood or Icom project you saw as a lead howto
article. In fact what was the last article on one of these manfg.
products that wasn't a review or paid advertisment?

And you really should move the unit to the base of the antenna or as
close as you can get it.

176. Re: Question: RF Speech Processing

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-07 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <821098902.19663@pinetree.microserve.com>
Source record: 108295

First, thanks to everyone for their comments on this subject. The RF processor in my previous rig was very effective and I'm looking for a way to build an inexpensive outboard replacement. Criticisms of the technique that I described are exactly what is needed. I think it would be useful to explore the various points that have been made in greater depth.

gary@ke4zv.atl.ga.us (Gary Coffman) wrote:

<snip>
>My gut feel is that it's important to use a carrier as high in
>frequency as possible for modulating and demodulating the DSB signal
>so that the percentage bandwidth is minimized and possible
>asymmetries in the frequency domain are reduced.

This is the first thing to consider, because it relates specifically to the decision of whether to use DSB. As in the previous example, let's say the carrier oscillator is 6 MHz. The DSB passband for audio frequencies out to 3 KHz will be 6 KHz. Therefore, the passband is 0.1% of the frequency of operation. If there are no tuned circuits between the balanced modulator and the clipping diodes, will frequency response irregularities due to non-symmetrical clipping really be a consideration? To go a step further, let's raise the carrier oscillator to something around 30 MHz. Now the passband width is only 0.02% of the frequency. Surely that would prevent this type of problem?

Looking at this somewhat empirically, the RF processor in my previous rig clipped the SSB signal at an IF frequency of 3.18 MHz. Because it was SSB, the passband width was approximately 3 KHz. That means the passband width was 0.094%, only slightly less than the 0.1% for the DSB processor at 6 MHz. If this percentage bandwidth can be symmetrically clipped for SSB at 3.18 MHz, would you agree that non-symmetrical clipping probably won't be a factor with DSB at 6 MHz, assuming the circuitry is otherwise similar?

>Another potential problem is reciprocal mixing in the demodulator.
<snip>
>The obvious solution to this problem is a lowpass filter between the
>clipper and the demodulator.
<snip>
>A clean DSB clipper thus may need a filter of 34 db.

Assuming the worst-case scenario of 34 dB is correct, the second harmonic products at 12 MHz are still a good distance away from the fundamental. Wouldn't something like a 7- or 9-element Chebyshev low-pass filter provide this degree of rejection?

>Splitting into sub-bands, processing, filtering, and re-combining is
>always the best approach. As long as correct phase between signal
>channels is maintained.

This points out some shortcomings in the split-band scheme that I hadn't thought of. I do have a few comments.

First, maintaining the correct phase at the output of each filter is probably impossible because the shift will vary across each filter's passband. I'm not sure how significant this phase shift will be in terms of the percieved quality of the recovered audio, but having been in the audio business a number of years, it's a troublesome concept. Multiple-band phase shift is one of the characteristics of graphic equalizers said by many (including yours truly) to degrade their sound quality. This may not be a significant issue in this application, but I'd be very interested in a critical listening test of the audio quality of one of these processors (with the filters active but the clipping turned off). To clarify this a little, I'm not just referring to the amplitude cancellation that takes place as a result of phase shift, but also to the audible effects of the phase shift itself.

Second, the possibility that the split-band processor might increase the overall percentage of harmonic distortion in the manner described above can't be overlooked simply by virtue of a low-distortion preamp/filter circuit. Most harmonic distortion encountered in audio is produced in microphones and speakers, not in the electronics. In this application, THD of the microphone will be impacted in the same manner as harmonic distortion produced in the input circuitry.

Again, I don't know just how significant this factor is. In double-blind A/B tests, it's been shown that listeners often cannot identify harmonic distortion in music until it is above 5%. Below that level, most listeners detect a difference between the pure and intentionally-distorted programming, but they fail to identify it as distortion. In many cases, they will describe a signal with 1% or 2% THD as sounding louder than the original, but not as being distorted.

Given the fact that speech lacks the sustained tones found in music, I suspect it is affected even less in terms of perceived distortion.

I have been placing the following circuit at the VCO
to clean up the power supply noise:

```
INPUT -+------- ------ OUTPUT
| C\ /E
| ------- MPSA18 or 2N5089
| |B
+--/\/\/--+
6.8K |+
--- 10uF
--- Tantalum
|
---
///
```

It has worked well on 3 VCOs so far.

There's a design for a mechanical relay in the RSGB VHF handbook (4th ed), but it's 75 ohm. The design uses a thin strip in a circular bore, and for 50 ohm the strip nearly touches the sides...

I recall some suggestions that a reed relay element in a suitable co-axial outer could be used as an spst switch, and two as a T for a changeover relay, (with the coil over the (non-ferrous) outer).
The resulting stub of maybe 1-2 inches on the open side should be ok on 2m.

Does anyone know what commercial 50 ohm relays use?

Mark,

There are TCXO's on the market (Temperature Compensated Crystal Oscillators)
in a DIL-14 house. A simpeler solution is to solder a PTC disc to a crystal
house. That way the xtal is stabilized at 60 degrees or so.

Siemens has appropriate PTC disks for this purpose.

>Hi all,

>I'm looking for an article that can help me in how to build a TNC...
>Regards,

>Marcos

I would NOT try to build one. Beside the cost involved you
would have to obtain the firmware (COPY?) from another
TNC and at least try to duplicate the HARDWARE from the
same thing. Your efforts and time could easily PAY for several
store bought TNC's, and mucho USED ones. I have purchased
two older TNC's recently for under $40 each.

If you want to play around with a cheap system for a newcomer
try the software (IBM-PC) TNC emulators of POOR MAN's PACKET
based on a TEXAS INSTRUMENTS TCM3105JL 1200 baud
half-duplex modem chip ($5-10) that operates on the computer's
PARALLEL PORT. It is a cheap, useable system (NO MAILBOX)
but will get you on packet for $0-30. Check out the PMP article
in the NOVEMEBER 1991 issue of 73 Magazine.

There is BAYCOM software (shareware version 1.5) and modem that
operates on the SERIAL PORT that provides DIGI-PEAT and
some mail functions as well file transfer protocals. This modem
will cost slightly more to build as it uses a few more chips to
interface to the COM port. Check out the BAYCOM TEAM's
WWW website for more info on this and other projects (they
offer a kit for sale. TIGERTRONICS has BAYPAC and others
listed in the ham mags have other BAYCOM modems for sale.
The BAYCOM modem can be used with other packet programs
(NOT ALL) with the use of appropriate BAYCOM drivers.

Last month's QST had an article about a cheaper BAYCOM
modem using the same modem chip called the IMP. The article's
schematic has a few errors and some things I did differantly for
all of the PMP/BAYCOM modems that I built (several). For the
beginner it is a good way to go, and even for laptop-packet
or as a second back-up packet setup. Also, drivers exist to
use these simple modems on other computer systems (MAC, etc).

Older 1200 baud BELL 202 compatible phone modems can
be found that can be converted (adding PTT circuitry, etc.) but
would be pretty bulky and hard to power for portable use. The
BAYCOM modems steal there power from the SERIAL PORT.

Hope that helps, good luck on any path you choose...73

Wes, thank you for a thought-provoking description of "selling kits"
from the other side.

Is anybody listening?

WRITERS AND KIT-SELLERS ARE *NOT* MAKING A HEAP OF MONEY!!!

Yes, for amateur radio projects in the magazines,
board layouts and source code should be available for cheap or for
free. No, we should not pirate this information for commercial
exploitation. Yes, we should be able to buy fabricated boards,
programmed PROMs, and disks containing the source listing.

Did any of you good ops out there try WRITING to the author of an
article in QST and requesting the "missing" information? You'd
probably be surprised at how a well-worded request for more information
-- in the case of "proprietary" source code, for example -- might
loosen up the availability of some info. Most software developers
are happy to tell you how they did something -- just like craftsmen
are happy to tell you what tools they used to craft an item.

But if you want somebody to do something for you, please be prepared to
pay their asking price.

Hi Ron...Hey it has been some time since we talked. I'll bet you are laughing at some of my efforts with the old TRS80 model 100, but the fool thing still works!! Regarding the MC68HC705C8, you might look in QEX starting at issue number 107 for Jan 1991. After that issue there were others in which contained terminals for RTTY, AMTOR were written up. The programming was difficult for those chips, three of which I still have not programmed effectively, but therein might be a clue for further investigation. Cliff Buttschardt W6HDO

>course, I can see how splitting the audio spectrum to enable effective
>filtering of harmonics could be as effective, but not more so.

I've still got a VOMAX which I used for years. In the tests I ran with it I was never convinced that it accomplished nearly as much as was claimed for it. I used it for whatever marginal benefit it might provide and because it didn't distort my signal too badly (although some people complained!)

The concept of speech compression is a fascinating subject. It is easy to compress a signal so that the average power is increased, but improving comprehension (the desired end result) is another matter; the two don't necessarily go together. In some instances compression can be counterproductive to comprehension or intelligibility. What happens is that compression of mid-band speech frequencies (generally not critical to comprehension) can drown out some of the higher speech frequencies (which are critical to comprehension). I believe this to be one of the shortcomings with the VOMAX and the reason why the on-air tests I ran never gave a decisive advantage to the VOMAX.

I've never had the occasion to use RF processing (other than simple ALC) so I can't provide a measure of comparison here.

For what it's worth.

>
>Charles Mott
>
>
>
>

It is not as complicated as some would imagine. The amplifiers are not truly hybrid bidirectional. A split system is used with diplexers at each side of the amplifiers. The most commom split is the sub split. 50-Max in the forward direction and 5-45 in the reverse direction. There are also two accepted standards in mid split systems. One is split at around 120 mHz and the other at around 250 mHz. These systems are mostly used in private campus situations where much of the bandwidth is used for telephony, networks and other forms of truly bidirectional communications.

Currently, only about 10 percent of the cable systems in the US have return signals and those that don't are very reluctant to upgrade. The current Dog and Pony shows about widespread high speed interactive cable services are dancing on thin ice...

194. Question: Neosid filters

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-08 00:00:00 UTC
From: Michael Petzold <M.Petzold@herts.ac.uk>
Message-ID: <4crm5u$171@helios.herts.ac.uk>
Source record: 108312

Hi there!

I've got a problem with so-called Neosid filters. I'm constructing at the time a weather satellite receiver, and I found a suitable description in "vhf communications", a British journal. Unfortunately it is a German development, so some country-specific components were seemingly used. In the schematic there are two different adjustable inductors (with core), and the author calls them Neosid filters. They have the notations 'BV 5056' and 'BV 5061', respectively.
Does someone know where I can get those filters (?) in the *UK* ? Or, of like importance, does someone know what values these devices have in order to replace them?

For suggestions or solutions, please e-mail to:

M.Petzold@herts.ac.uk

Thank you!

Well, I built the kit and was very happy with it. I had no problems with solder connections. The traces are fine (as in thin!) but seem to work for my setup. I run the tuner under my ICOM IC-706 in my old S-15 Jimmy and have had it in there for a few weeks now with not one problem. Time heals all wounds and, in the case of the tuner, may open some... I have had some correspondence with Dwayne and expect if a problem were to develeop I could count on him to provide any assistance possible. I would not only built another (if I needed it) but have heartily recommended it to my friends locally. It sure beats the old MFJs!

As the designer of a unit similar to the VOMAX, I feel compelled to respond. The literature I have on VOMAX claims 10-12 dB improvement. One might ask what is meant by "improvement", to which I would respond, based on Schreuer's February 1971, Ham Radio Magazine article: intelligibility gain. OK, what does this mean, you ask. Good question. Difficult to answer.

>The concept of speech compression is a fascinating subject. It is easy to
>compress a signal so that the average power is increased, but improving
>comprehension (the desired end result) is another matter; the two don't
>necessarily go together.

Well, it isn't easy to do it correctly:-) Increased average power and improved readability are not necessarily mutually exclusive though. I normally dislike anecdotal testimonials, but I don't know how to avoid them in this case, so a couple of personal examples.

When I first tried my processor, I was using a 100W transceiver. I didn't own a linear amplifier, but I had the loan of one. I ran a number of on-the-air tests whereby I would ask the other op to compare signal strengths and intelligibility. I would first use the 100W with no processing. I would then turn on the amplifier (SB220) and get a report just to verify how much signal strength change he reported. I would then tell the other guy I was trying out this new audio filter design and I would like to know what he thought. I would turn on the processor and TURN OFF the amp and ask for a report. Almost invariably, the signal strength report was the same and the comments would be something like "The audio has more punch" or "You sound a little bassier" or "You're not quite so natural sounding", etc. I never got a report that suggested that I had dropped power by 10 dB.

I serendipitously chanced upon another fellow, who was using my design, on one of those old ten meter paths where the signal is S1 but Q5. I asked him to turn off the processor so I could get a feel for how it sounded in the other direction. When he did, he was GONE. I mean gone. There was nothing. He had to

turn it back on to tell me to go ahead. We did this several times in both directions with the same result.

Again the disclaimer. I do mostly weak signal VHF work and I have no lab data to back this up, but I'm convinced, that a good processor, intelligently operated, is equivalent to adding a linear amplifier.

I'm not clear on what you mean by this. Advantage over what? There was one letter to Ham Radio Magazine from K3ND which discussed comparative tests between the VOMAX and my design. Gale reported a preference for my design in 90% of the cases. Most of his respondents believed that the VOMAX frequency response was too narrow. Perhaps this is the problem in your case. There is a trend to narrower and narrower filters in modern radios. Coupling these with further BW limiting in an outboard processor might cause problems.

Hi Jim, This sounds like the boards I get from out of house layout shops that never work with RF. That's too bad. Maybe you could point that out to the kit supplier, because your observations illustrate a big problem. Somewhere I heard the rhyme short and thick does the trick. I assume that meant RF traces.

201. OLD 20M HB SSB/CW XCVR - early 60s?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-08 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfDKvFt4.6Hp@netcom.com>
Source record: 108319

Somewhere in the 1960s (I believe) there was published a design article for construction of a SSB transceiver. It was all solid state, was intended for 20 meters, was about 1/4 watt output power, and specifically was designed to run from a 6 (not 12) volt power supply. It was about the size of a cigar box as I recall, and the author had intended to use it in his Volkswagen bug, hence the 6 volt power supply limitation. I'm trying to track down the article with this limited information. If you recall seeing something like that in one of your old magazines or handbooks, could you let me know the reference, or even better yet make a copy of the article? I think it was the first published design for a all solid-state transceiver for SSB, and I'm interested in duplicating it.

202. Funky bias setup in VHF linear amps?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-08 00:00:00 UTC
From: jdc@cci.com
Message-ID: <DKvJIL.67F@sunsrvr6.cci.com>
Source record: 108320

The schematic for a Mirage 2-meter linear amp shows a bias arrangement that looks peculiar.

There is the usual rectifier diode from transistor base to ground with a fixed resistor and trimmer potentiometer in parallel. This part looks normal.

What was odd was the bias supply: Instead of being fed by a DC voltage it was connected to the transistors collector through (here's the wierd part) a series resistor, capacitor and choke.

How is this supposed to work? Are they siphoning off some of the output signal and letting the parallel diode rectify it?

I'll defer to Wes on this, but briefly when clipping is done at audio, you
can process small bands that are are less than one octive wide. Harmonics
from clipping not only fall outside the passband of channels, but mixing
is reduced because there is little likelyhood two tones will appear in one
clipping channel at any one time.

RF clipping does not do this, unless the processor has several very narrow
filters feeding separate clippers.

>
>

Hi Jack,

Vomax did this by having the "after clipping" filter shift the phase back
at the same slope as the pre-clipping filter. At RF phase control would be
easier, but the filter cost would be pretty high.

I don't see how phase shift would be a problem with DSB as long as a
narrow RF filter is avoided, but then the worry would become the lack of
signal filtering. There must be some BW control before clipping. Perhaps
an audio bandpass filter before the balanced modulator would help, since
as Wes said, the lows should be rolled off a bit before clipping and we
all know clipping out of band audio just adds needless distortion.

I'm working on a DSP based processor now, in between 999 other things.

>circuit?" And I answered, "Beats me :-)"

Well, I don't know of any deliberate simple controlled way to do it either,
but what I'm talking about is unintentional and undesired behavior. In
broadcast we call it incidental phase modulation, and it's the result of
sending the signal through a somewhat non-linear system. The phase shift
induced in the two sidebands is different, because they are on different
frequencies, and varies with signal level. When they recombine in the
demodulator, their vector sum is different from the input signal too.
Through a system that deliberately operates non-linearly, the effect should
be much greater.

>>Depending on how the clipper is implemented, there can be considerable
>>differences induced in the phase/amplitude envelopes of one sideband and

>they are. The split-band approach doesn't suffer this particular problem.

I agree with this, of course, but I think this high order multiple
mix will be of considerably lower amplitude than the straight products
the filter would remove. You'd need some sort of circulating tank to
keep the base products around to remix with each other to form tertiary
products sensible to the demodulator. I don't think most clipper circuits
have enough tank to do that to any significant degree, but perhaps the
very filter I'm suggesting might supply that tank.

211. UHF noise source

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-09 00:00:00 UTC
From: Allen Wallace <allen@dtint.dtint.com>
Message-ID: <4cutud$gc8@itchy.itsnet.com>
Source record: 108230

I've got a 1960's UHF noise source which I'd like some information.

It has a tube labled TD-44/7988 and is about 18 inches long. The assembly has two UHF connectors, The tube has two wires.

How did these old noise generators work? what voltages did they use? How much excess noise did the generate?

Thanks,

73

Allen Wallace, N7CGH

Being connected to the collectors may not mean they're using feedback.
The collectors are probably connected to the positive voltage supply
thru an inductor with a cap in parallel. If the bias gets it's
voltage thru another inductor, the inductor probably blocks the VHF signal,
the cap probably goes to ground to provide an Ac (RF) ground, and the
resistor helps limit the current. This all depends on how large the
inductor is, the larger the L, the less VHF gets thru. It may actually
be a feedback loop to help linearize the amp at VHF and help eliminate
UHF parasitics, but it's hard to say without a schematic and some component
values.

Don't depend on the schematic to be absolutely correct. What Mirage amp is
it? I'll look at one and tell you how the circuit works.

214. FS: Miniature Vaccum Relays 5KV 15A SPST Latching $20

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-09 00:00:00 UTC
From: Steve Sawyers n0yvy <sawyers@inav.net>
Message-ID: <4csuu3$482@composer.inav.net>
Source record: 108233

FS: Miniature Vaccum Relays 5KV 15A SPST Latching

I am not sure this is appropriate for this
newsgroup, but these are definitely builderï¿½s
parts and there has been a lot of discussion the
QST antenna article which prompted me to buy
them.

New Miniature Vacuum Relays

Manufacturer: Kilovac
Model : K41P
Contact: SPST Latching

Contact Ratings:
Freq Volts AMPS
DC-60Hz 5,000 15 A
2.5MHz 4,500 12 A
16 MHz 3,500 8 A
32 MHz 2.800 6 A

Contact Capacitance
Between Open Contacts 1.2 pF
Open Contacts to Ground 1.2 pF

Coil Voltage: 26.5 VDC Momentary
Coil Resistanc : 80 Ohms
6 ms minimum pulse
Not for Continuous Duty

Operate Time Max: 6 milli-seconds

Shock load rating: 30 Peak G's

Operating Temp.: -55 to +125 degrees C

Mechanical Life: 1,000,000 Cycles

Nominal Weight: 1 oz.

These are approximately 1/2ï¿½ in Diameter and 2ï¿½
Long. They are designed for Mid body flange
mounting, and mounting must be grounded.

Note: There are two coils, one to open and one to
close. Coils can only take a pulse, as continuous
loading will fry them, but it only takes a 10 ms
pulse to kick them on or off.

They are used in military automatic tuning couplers. They are new in factory boxes of 42 each. I stumbled across about 1000 of these and had to buy them all to get what I wanted. So decided to sell the excess. I have about 300 of them left, but may be able to get more.

Will sell any quantity.

Price: $20 Each

$5 Shipping and $5 COD (if applicable) per order
Free shipping and COD of orders of 10 or more.

I called KiloVac and they are quoting $75 each in quantity 100, Jennings has a similar part at $48 for quantity 100.

Best installation is to mount thru a drilled aluminum plate to provide shielding between high voltage RF and control voltage.

I am going to use them for a high power version of the QST automatic antenna tuner. Will need to beef the coils and caps, but the micro processor won't care. It does take a circuit mod to drive two coils on the transition rather than one via level, and the sensor needs to be redesigned. Am also going to use for tower mounted switch boxes using a 3 to 8 decoder and a little driver logic.

I am sure other people have other ideas.

Allen:

I could be (and probably am) way off here, but this sort of sounds like a gas discharge system. In the ancient past, we used waveguide versions which had a gas filled tube inserted at an angle through a waveguide. One end was terminated and the other was the output spigot. I seem to remember ENRs of 15 dB or so. We had systems by both HP and AIL. If this is a gas tube, then it requires a high voltage pulse to fire it. I can't remember what "high" means any more though:(One caution: if it is a gas tube and you learn how to power it, these were very likely to generate voltage spikes at the output which would be instant death for modern solid-state devices.

>range!

My criticism, which I don't think I've tossed into this particular iteration of the "no source code available" discussion, is a little different.

Just as any construction article contains a schematic of the hardware components, the source code is analgous to a schematic of the software components. Seeing the details of both can be quite educational; seeing the details of how one designer elected to split functionality between the two is especially useful.

Making embedded code invisible discards a very important learning opportunity.

>Ron, w8gus.

You are right, I could not find that spec in the data book, either.
However, another source is the Technical Documentation, available on the
Web at http://design-net.com/csic/Tech_data.html , one of Motorola's many
resources. You have to register, which is not much of a chore. The
documents are in PDF format, so you need to get the Acrobat reader from the
Adobe site. There is a link at Motorola. Make sure you get version 2.1 .

The spec you need is : @Vdd = 5 volts and Vss = 0 volts, Vpp = 14.5
volts min. , 14.75 volts typ. , and 15.0 volts max. Thes figures are from
the electrical specifications section. The document is also much more
descriptive of the various features of the processor.

I also don't understand why QST would publish an article for
a project that you can not get a part for from somewhere other then
the author at a high price. what if I already have a chip and the
ability to program it. I do not care to see the source code. If he
could have provided a binary file to download from arrl BBS at least
then I can program the chip myself.

The removal of diode modification certainly extends the TX/RX capabilities of the radio, however, I think the unit scans at a slow rate. Has anyone discovered a way (via swapping a part or other) which will change the rate? I will probaly end up calling Grove's to see if they know of a way to solve the problem, however, I wanted to ask here first.

Hey!
You actually have an amplifier that uses the 4CX250Rs???

I have about 50 of the tubes still in the sealed cans.

I have the varian spec sheet for the tubes too.

What freq. range was the amplifier built for?

I have wondered about this too. I know that multi-band processors
are used to reduce the dynamic range (eg. in Dolby A and in more modern
variants), but usually it is about reducing the dynamic range from, say
60 dB to 40 dB for storage on tape etc.

However, if you are going to use aggressive clipping to reduce the
peak to average ratio, I do not see how tis would improve the situation
a lot. If you split the signal into multiple subbands, clip each of them,
filter out any out of band harmonics and combine the subbands into a
single stream for transmission, you can still get some nasty high peaks,
if the phase relationship is unfavorable.

Think about a simple waveform consisting of frequencies f and 2f and both
have the positive peak at the same time (this resemples the speech
waveform). aAssume that f and 2f fall into different subbands as clean
stable sinus signals with no need for clipping. Summing these signals
and you get a positive peak twice as high as the individual signal. This
corresponds to four time peak power in an SSB transmitter compared
to a single tone. You have gained nothing with a multiband clipper.

[About DSB clipping]

> I thought about that too, but I don't see how the distortion products

> modulator is operating at 6 MHz and that it's modulated with a 1 KHz
> tone. The output will be two carriers (DSB), one at 5,999 KHz and
> the other at 6,001 KHz. What combination of those two carriers
> produces a distortion product that falls near the two fundamentals?

How about third (and 5th) order intermodulation products ?
2*6001-5999 = 6003 kHz and 2*5999-6001=5997 kHz and after detection
you have two signals at 3 kHz.

However, a single tone is not a realistic test signal for a clipper.
Assuming a simple two tone signal with 400 Hz and 1000 Hz tones, you get

in addition to the 3rd order products for the 1000 Hz tones (as above)
also the 3rd order products of the 400 Hz tones.

Calculating all the intermodulation products up to the 5th order,
will for the DSB case products produce within +/- 4 kHz of the DSB carrier:

<deleted 41 intermodulation product below 6.000,
which are images of those above 6.000>

3rd order 6.0002, 6.0010, 6.0012, 6.0016, 6.0018, 6.0024, 6.0030 MHz

5th order 6.0002, 6.0004, 6.0006, 6.0008, 6.0008, 6.0010, 6.0012,
6.0016, 6.0018, 6.0020, 6.0022, 6.0024, 6.0026, 6.0030,
6.0032, 6.0032, 6.0036, 6.0038 MHz

After the product detector you get intermodulation products practically
every 200 Hz.

In SSB clipping the only intermodulation products that fall within
4/- 4 kHz of the carrier are:

3rd order 5.9998, 6.0016 MHz
5th order 5.9992, 6.0022 MHz

if there is an USB filter after the clipper, the only audible IM products
are 1.6 kHz and 2.2 kHz.

If you run the test with more tones that are not harmonically related
to each other, the difference is even more evident.

I couldn't say, because one case is SSB and the other is DSB. There's more than just bandwidth at stake here. SSB demodulation is just a down-conversion mixing process. If there are phase shifts between the highest and lowest frequencies, you just get a little time distortion, IE the old click-boom effect familiar to users of horn speakers. But DSB demodulation is different. There, the output audio is the vector sum of the two sidebands with respect to the reinserted carrier. If one sideband is phase delayed with respect to the other, amplitude distortions and waveshape changes occur in the output.

Any shaping done after modulation and before demodulation may result in a phase delay between the matching components of the sidebands, and that will in turn lead to amplitude and waveshape distortion in the output audio for DSB. I believe the correct factor we should be concerned about is called group delay.

The classic example of this occurs in a VSB TV transmitter. You'll get a nasty spike on the tip of sync when you demodulate the signal because one sideband is delayed differently than the other through the transmitter. The cure requires *predistorting* the modulating waveform so that the incidental phase delay introduced by the system is cancelled out. The bandwidth for a channel 11 transmitter and H sync is 0.015%, but that's not the important measure. The important measure is the differential delay through the system. That only needs to be a few degrees

at 200 MHz, a very small time difference indeed.

Be really careful here. I recently had to perform a failure analysis on a VCO hybrid manufactured by a *very* well known semiconductor and hybrid house. For obvious reasons, I must be necessarily vague about some of this.

Under certain conditions, of temperature, voltage and phase of the moon, we were experiencing severe spurious sidebands on the UHF output. This device used a Motorola 7812 chip as the voltage regulator and I pretty quickly ascertained that the regulator was oscillating and modulating the VCO.

Because our application specified certain immunity to noise on the supply voltage to this device, the hybrid manufacturer used an emitter follower as described above to pick up a few dB of noise rejection. Because of space limitations, he had room for only one filter capacitor (.33 uF tantalum) so obviously, he used it on the emitter follower base. However, Motorola specifies a minimum of .33 uF on the input of the regulator chip for stability. Conversations with a Motorola application engineer confirmed this.

By wire-bonding the cap directly to the regulator input, I was able to stabilize the regulator, confirming that this was the problem. Lesson learned:

The capacitance multiplier idea may work sometimes, but without *very* careful analysis, you might get into real trouble.

Regards,

Wes -- N7WS

>then I can program the chip myself.

I would not characterize the charge for the chip as "high price" -- the author offered it with a socket for $20.00 -- perhaps a few dollars at most over the unprogrammed device cost.

Don't get me wrong; I agree with those who are telling us all that a construction article is more valuable to the reader if it has source code. I agree with the relative few who will scrounge all the parts and program their own microprocessor that an article that is essentially a technical description of a kit is less valuable than one that is more complete. When the author offered the block diagram, I think we erred in not making the block diagram available somehow. I agree with those who feel that as a matter of principle QST should publish articles that are educational.

I have to wonder, however, whether that principle should not be flexible. I have heard from a number of folks who are glad we ran the article, because even with its lack-of-full-information flaws, it was a useful article. Would it really be right for us to see a really neat construction-project article and decide that we were not going to share it with anyone because a relative handful of people who want to program their own IC think that we should not? For old construction pros like you and I, it is a big deal to program our own IC; for many of the newcomers, it is a big deal to pick up a soldering iron and build anything useful at all. Perhaps we can say that this article was written for them, and if we feel an aritcle is not useful because it is missing something, turn the page and move on to the next.

I have been somewhat surprised to see some of the turns this thread has taken. I have seen a few posts that seem to imply that because QST *occasionally* has run an article that doesn't offer source code, that *none* of our articles are complete. In reality, over the past three years, QST has, if memory serves, offered two articles that didn't include source code. FWIW, those two have proved to be among the most popular construction projects, based on the semi-formal counts we always get from the authors. I think that tells me that we have chosen the exceptions to our informal "rules" wisely. (We *do* encourage all authors to make source code available, and will continue to do so. We have even

changed a few minds along the way.)

All in all, I think QST offers a good balance of articles, ranging from some higher-tech articles, lots of articles for the middle ground and a substantial section of articles that are chosen because they would interest newcomers. (Now, for me, the DXCC and contest results hold little interest, but I just assume they are there for someone else and let it go at that.) I would join the howls of protest if all of our articles became the "buy the kit" articles, but really don't mind seeing the occasional gem that is like the auto-tuner-kit article.

Ok I will make a fool of myself. Maybe someone can correct me but I
seem to remember that a Mercury vapor lamp (florecent lamp) can be used
as a noise generator. You can calculate the noise temperature from
the lamp current. I seem to remember that DC was used to power the lamp.
I think this design goes back to the 1950 - 1960 time frame.

>since I looked at them, but when I did they almost were worthless for
>power line protection.

Typically a MOV will be in hard conduction at 150% to 200% of its
rated working voltage, IE for a V130 that would be 195 to 260 volts.
It'll reach hard conduction a few nanoseconds after a transient reaches
that value, and remain so until the transient decays (up to the peak
joule rating of the device). Now assuming the PS being protected has
a dV/dt longer than a few nanoseconds, the transient will be safely
clamped before damaging voltage can pass through.

Remember a MOV isn't intended to be an overvoltage protector,
it's a *transient* surge protector. It won't protect a PS if
the line voltage rises to 140 volts for a sustained time, but
it will keep transient peaks below values that could punch
a junction or an electrolytic cap in the supply. (It is assumed
that a good PS design will use parts rated for peaks at least
150% to 200% of their planned sustained voltage.)

And, based on the Motorola Micor standard of documentation: test and alignment procedures, test equipment, circuit revision lists.

The last thing I do for any homebrew project is to draw up a nice, neat schematic, by hand or Postscript. I put in a few annotations to help explain anything that might be good to know down the road. If possible, I also make a little bitty photocopy of this to tape inside the cover of the project itself. I have them all together in a 3-ring binder next to my workbench. If I want to modify a circuit, the schematic is in my hands in seconds.

: If so, are the schematics (or construction acticle) available?

There are several manufacturers of ICs that do most of the job. For example, if you just follow the circuits in the Maxim data sheet for the MAX712/713, you can build a "universal" charger that you switch the number of cells on, or a "custom" charger for a fixed battery size. They show both switching and linear types of circuits; the linear is far simpler and I'd say to go with that unless you really need the power efficiency. DigiKey lists these parts at just over $6 each. I couldn't say if the Maxim parts are the "best", but they should be available and seem to do a reasonable job.

Source record: 108175

Hi

Interesting discussion ... I built one of Wes' Split band speech processors and I'm still using it - works great - thanks Wes.

An idle thought regarding comprehension. Has anyone tried using formant filters rather than just 300-3000 speechband filters? I'm mainly thinking about receive filtering but possibly in a processor as well. I vaguely remember a simple RC filter years ago (from NASA) that was supposed to put notches into the transmitted audio where there shouldn't be any speech info.

Ring any bells?

Cheers

254. BFO Project Questions ?????

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-11 00:00:00 UTC
From: "Brian C. Dolan" <bdolan@netwest.com>
Message-ID: <4d1rnv$81i@news1.netzone.com>
Source record: 108176

I recently downloaded a small schematic for a BFO synthesizer add-on for SW receivers, that I found on a QRP related site. Within the brief text associated with the schematic, it states:

"The heart of this project is a 455 kHz IF transformer: go to your closest junked broadcast radio receiver and steal one from there."

Not knowing what a "455 kHz IF transformer" is, and being an inquisitive guy, I pried open the nearest cheapo AM radio and found some things I recognized, and some I didn't. Process of elimination led me to rule out the resistors, capacitors, coils (chokes?) and transistors. This left the metal "cubes" (7 in this case),each with a hole in the top. In the hole is something with a flatbladed screwdriver slot in it. Is this an IF transformer? If it is, can someone briefly explain what it does? Additionally, each one has a different color in it; what does the color signify? (...maybe the 455 kHz aspect ???)

Later in the text, it states:

"Adjust the transformer slug until it resonates at 455 kHz, which can be accomplished using a receiver or GDO. AS you tune the slug (using the receiver) you should hear the heterodyne note of the BFO lowering in pitch until it eventually zero-beats."

This section left me scrathing my head. I assume it has something to do with those screwdriver slots, but I have no idea what it's trying to get me to do. How would I use a receiver to do this? What is a GDO? What is "zero-beats"?

Answers to the above questions, as well as any general advice would be greatly appreciated.

Thanks in advance for helping a new ham,

Brian

262. Xpert Needed:Zener Diodes --- Can you make what you dont have?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-11 00:00:00 UTC
From: pfzouave@aol.com
Message-ID: <4d4ik0$po5@newsbf02.news.aol.com>
Source record: 108184

Question: Im looking at a reset circuit (suggested by Microchip, the manufacturer of the 16C74 microcontroller) which is build around a PNP transistor, three resistors, and a zener diode. Basically, the zener is set up with a series resistor to form a voltage reference of sorts. It feeds the transistor, which in turn can activate the reset pin on the processor.

The idea is this: If Vsuppy falls below the zener voltage + 0.7 volts (drop across the transistor, I presume), then the transistor will shut off and a pull-down resistor will yank the reset line to ground and reset the processor. So far so good.

My problem is this: The processor is spec'd to work down to 2.5 volts. If I add a safety margin and say the minimum before reset should be 3.o volts, 3 - 0.7 leaves me with a required zener voltage of 2.3 volts. I have several catalogs laying around here, and can't find any zeners less than 3 volts.

Can I synthesize the breakdown characteristics of a reverse biased 2.3 volt zener by replacing it with three *forward* biased switching diodes (like the 1n4148?). If the drop across each switching diode is, say 0.7 or 0.8 volts, then the total drop across the string should be 2.4 ----- very close to the zener voltage id like to see.

Will this work? What practical problems are there with this approach? How consisent is the forward drop of a particular line of switching diodes from batch to batch?

Please email any thoughts you might have, as my access to newsgroups is often less than reliable. Pete

>interest newcomers. (Now, for me, the DXCC and contest results hold
>little interest, but I just assume they are there for someone else and
>let it go at that.) I would join the howls of protest if all of our
>articles became the "buy the kit" articles, but really don't mind seeing
>the occasional gem that is like the auto-tuner-kit article.

I think it is a good advertisement. But ads don't belong as the
feature article in the *technical* section of the magazine. Perhaps
you could stretch a point and put it in with the other *product
reviews*, or give it coverage in the *New Products* section, but I
really think it belongs in the back with all the other *paid* advertising
by kit manufacturers.

Whether this is a great kit or not isn't the point, whether it is
a popular kit or not isn't the point, whether it is an economical
kit or not isn't the point. The point is that this isn't a technical
construction article because the primary information that makes it
an *auto* tuner is hidden from the reader. It's an ad, and QST used
member funds to *pay* to run this ad. That's not how it's supposed
to work. The company is supposed to pay *QST* for advertising space.

Firmware is virtual circuitry. Withholding information about the
firmware in a construction article is no different from withholding
schematic diagrams. Would you support paying for and publishing
a construction article that required the reader to buy the schematic
separately from the article author? (I might, that's essentially
what you're doing when you use any commercial IC. If you want the
internals, you have to buy the manufacturer's data book.) But more
to the point here, should you print a construction article where you
can't obtain the schematic, even from the author? I think not, that's
like the magic antenna tuner which was just a glob of expoxy hiding
a power resistor that QST correctly X-rayed and brought to public
attention a number of years ago. (Note: that's not a totally bogus
idea in certain special circumstances, but the way it was presented
bordered on fraud because there was no way to determine how it worked
thanks to the deliberately hidden internals.)

Source record: 108187

A thought occurred to me regarding the source code issue for this article. One of the problems is that it is so easy for a commercial outfit to simply lift the code as is and make profits from what was intended to be freely distributed. As a software professional, I would be really hot if something I wrote in order to give away for the benefit of the fraternity were used for profit by someone.

There is a way to protect the rights of the authors and still allow free distribution for amateur personal use. All the author has to do is to copyright the source code for the program. QST should have the policy that they will publish articles containing copyrighted software ONLY if the copyright holder grants a license to use for personal use only.

I would encourage authors to incorporate the "copyleft" of the Free Software Foundation. This is a more restrictive copyright. It says that if you modify the software for your personal use and make improvements, you must share those improvements freely with others. This is the spirit of amateur radio at its best, IMHO.

BTW, the article was a really neat idea. I may build one similar soon.

Ramsey Electronics sells a RF sensing switch (I think that's
what you're wanting) called the TR-1 for 15 bucks.
1-800-446-2295
There's not much to it, just a rectifier that takes a small
level of RF (thru say, a 5 pf capacitor) and biases a
transistor on to activate the associated relay coil.
You should be able to find details of such a circuit in the
ARRL handbook etc.

Source record: 108191

Hello all:

With the scarcity of the 32-S3 series transmitters, I was thinking about purchasing a 32-S1 transmitter instead. However, I heard about complaints regarding the CW operation of the rig. From what I gather, CW is currently generated by the use of audio tones sent to the sideband generator and out the rig as opposed to using actual carrier for true CW. If this is the case, I am thinking about designing an oscillator/keyer scheme to circumvent this circuit, but before I do, has anyone done such a modification or is there any information to mod the S1 to S3 specs?
73's. Cal.

Tough power level. Cheap plastic case devices only seem to do
500 to 600 mW output. Most people seem to settle for that and
run this into a surplus GaAs FET or expensive hybrid module to
get 4 to 10 watts output. The 1995 Microwave Update Proceedings
(ARRL #5366) has a +28 dBm design by AA5C using the Siemans CLY-5.

Many GaAs FETs will work just fine lower in frequency, but
the impedance matched ones never seem to tune up the same
way. No problem for the "real experimenter," make sufficiently
long 50 ohm input/output lines and tune till it works!

Of course, the M67715 hybrid will easily put out a watt linear,
but I don't think this is what you want.

Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

Does the copyleft protect the authors from someone else using the code in a commercial product, or just specify that all changes, as well as the original source must be made available?

The article has got enough information to be useful as it is, both as a kit and as food for thought, and I don't fault the ARRL for publishing it, but it's frustrating that to do anything with that, you'd have to reconstruct the code, instead of being able to build on what's gone before.

It looks to me as if the MC68HC811E2 is compatible with the -A1 part used in the article, and has 4 times as much EEPROM for the code. This would give lots of room for additional functions. Also, the PD0 and PD1 asynchronous serial port pins are just connected to each other, and with the addition of an RS-232 converter could perhaps be used to connect to a computer, or other remote controller.

I also wonder why, apparently, the unit stops tuning when it gets to a specified level, and doesn't actually continue to find best match.

In addition, there seem to be four more A/D ports available, and I wonder if a phase detector or other sensor could be added to make for an even more efficient match hunting algorithm.

My preliminary checking indicates that developement hardware and software for these microprocessors are readily available and cheap. Check out "Nuts and Volts" or the 68HC11 microcontroller FAQ.

Also, if you just doubled the values of the capacitors and/or the inductors, how much would you trade optimization of match for extended capability on 160M (how much extended capability)? This version doesn't require the code, BTW, just the kit, a couple of capacitors, and some wire. If you were willing to sacrifice some of the indicators (use an external SWR meter, say), or use the async port for control and status, you could, I think, extend the range on 160M, without sacrificing optimization, but this again requires modifying the code.

I rather wonder if I'd have paid as much attention to the article if there hadn't been so much controversy about it.

I would encourage authors to incorporate the "copyleft" of the Free

Software Foundation. This is a more restrictive copyright. It says that if you modify the software for your personal use and make improvements, you must share those improvements freely with others. This is the spirit of amateur radio at its best, IMHO.

BTW, the article was a really neat idea. I may build one similar soon.

Thanks Tom, this is exactly what I was looking for. I have a couple MAX713's on the way. I looked through MAXIM's 1995 book, but I did'nt realize that thay dont reprint all their parts in the current data book. The MAX713 is in the 1994 data book. What other manufactures make this type of IC?

274. DC/AC (Inverter) Schematic?

I am looking for schematics for a high amp DC/AC converter to use in
the field.
It should take 12VDC in and produce 120VAC 60Hz out at 1600 watts.

I realize the best way to do this is to have a design with a single
'signal' card
and multiple 'driver' cards. Each 'driver' card could procude 100W
and take it's
60Hz from a common source.

Anybody have an expandable design like this?

Dave Covert, KB5GOG

Eric -

Forgive me, but I'm not up on model numbers. If a TH-78A is a HF transmitter or receiver, the ARRL Handbook has had plans for an interesting T/R switch in it for the last several years.

I assume the emitter follower precedes the 7812? That's interesting;
I'd probably put it after the 7812, in an effort to reduce the 7812
noise voltage. That doesn't solve the problem you found, though.

Yeah; like, pay attention to the manufacturer's specs. The 7812 input
"port" needs to have .33uF connected; I'm sure the capacitance seen
looking back into the emitter follower is much less than .33uF. Of
course, depending on the base resistance, the capacitance seen looking
into the emitter is much less than .33uF, also. Which makes me naively
suggest that "capacitance multiplier" is a misnomer.

I used a ICS1700 charger chip. I think it is very similar to the Maxim chip. It uses a "Reflex charge" (90% +
charge current, 5% -charge current, 5% measurementcycle) that minimizes gas build-up during charging.

Motorola, Benchmarque and Sanyo also have a similar chips.

The problem with companders and numerous other schemes is that they
require "inverse" processing at the receiver. In other words, they're
only useful if you're communicating with a station similarly equipped.

>the original source must be made available?

The latter. It also prohibits charging for the code, though a media and distribution charge is allowed. Thus someone can't take your program and go sell it, but they can charge a media and distribution fee to *give* it away.

Copyleft is a powerful idea, born of concepts of academic freedom. It encourages development by allowing access to the work of others so you don't have to constantly be reinventing the wheel, but can stand on the shoulders of giants while making your contribution. It also, due to the mandatory source availability, is a powerful teaching tool. It allows anyone to see how things work, and how a particular problem might be addressed by a practitioner in the field.

This latter is particularly important to an organization like the ARRL which maintains its tax exempt status by claiming to be an educational organization. If they wish to teach us about *auto* tuners, then they'd better show us how the *auto* part works. Trade secrets have no place in a tax exempt educational organization's lead publication.

That particular radio has several different models. The first three digits of the model number will tell a person which band it is on. To find the frequencies in the radio, you should look under the belt clip or remove the BACK cover and look underneath. If this does not produce a fequency list, you will need to take it to a radio shop and have the the prom read. You should know your own frequency and PL or DPL codes when you go. They can re-program the unit (probably for the same charge) at the same time (if the units are compatible). The shop I used to work at charged $35 to do this. You will probably have to go to a MOTOROLA shop to have this done.

Nice response Ed! That's a tough job, to satisfy everyone.

But I still have a question. Can anyone post or E-mail a flow chart of the software? I am trying to find out how the author handled that interesting part of the problem. Does anyone that built the tuner understand how the software works enought to describe the basic idea behind it?

Your best bet for a reliable reset circuit is something like the Maxim MAX704T/S/R or the reset chip. The T/S/R suffix is the reset voltage (3.06, 2.91, 2.61 respectively). Don't use the plain MAX704, it resets at 4.65 volts. The one you describe has problems with temp drift and good reliable operation when conditions become marginal or you have a funky power supply during turn-on. Maxim and others have a whole bunch of microprocessor reset circuits which work better than any of the popular discrete designs. I think the cost is about $5.00 each.

>It'll reach hard conduction a few nanoseconds after a transient reaches
>that value, and remain so until the transient decays (up to the peak>
>joule rating of the device).

Could you please give me an example of what the "hard conduction"
resistance is?

What is the "on" resistance at say...300 volts peak for a MOV that will
safely opeate on a normal 120 volt power line (say 180 volt peaks). Do you
have the exact specs?

The last time I looked at the data from manufacturers of MOV's, they were
about worthless! Transformers would have been into saturation way before
the MOV conducted, and the transformer's saturated impedance would have
been several times lower than even a very large MOV's "on" resistance.
Maybe that has changed in the past few years.

Do you have data that indicates a MOV that can protect a transformer
operated supply? I understand MOV's help on line operated devices without
a transformer (they are better than nothing), but what about if a
transforer is used?

73 Tom

Now assuming the PS being protected has
a dV/dt longer than a few nanoseconds, the transient will be safely
clamped before damaging voltage can pass through.

Remember a MOV isn't intended to be an overvoltage protector,
it's a *transient* surge protector. It won't protect a PS if
the line voltage rises to 140 volts for a sustained time, but
it will keep transient peaks below values that could punch
a junction or an electrolytic cap in the supply. (It is assumed
that a good PS design will use parts rated for peaks at least
150% to 200% of their planned sustained voltage.)

>
> Thanks in advance for helping a new ham,
>
> Brian
> KC7JRT
>
Well, Brian, you may have a fun time of it. First, question...
Yes the IF transformers will look like little metal cubes with a
hole in them and a gray or black ferrite core inside that can be
adjusted. The core is in the middle of a coil of wire and
adjusts the inductance of it to tune the transformer. Some
cores have a screwdriver slot and others have a hex shaped hole.
I'm not sure why there would be seven if its just an AM only
radio. I would only expect 4 or 5. They are not all identical,
and are color coded for function, and or frequency. If the
radio is an AM/FM radio then some of the transformers you see
are probably for 10.7MHz instead of 455KHz. (usually FM
receivers use 10.7MHz for IF, and AM uses 455KHz).

For your case, I would expect that any of the 455KHz
transformers should work in your application. The difference
between the various 455KHz transformers is in the turns ratio
and taps to couple into the next stage. I expect that the
circuit that you are building only uses the primary winding on
the transformer; so you may have to figure out which pins to
use. You could use an ohm meter to determine which pins are
part of the same coil of wire.

As for the "beat". If you build up the circuit and connect it
to a radio and then tune in an AM radio station; then when you
turn on the BFO circuit you should hear a loud squeal (at least
you will if the bfo is near the 455KHz if of your working
radio). Then as you tune the bfo by turning the adjustment
screw the squeal will move up or down in frequency. The squeal
is the "beat" frequency - the difference in frequency between
the bfo oscillator frequency and the radio's IF frequency. You

want to adjust the bfo frequency until the beat frequency approaches zero (the squeal gets lower and lower until it disappears - if you keep tuning then it starts getting higher and higher again).

The GDO is a Grid Dip Oscillator, which is a general purpose test instrument that can be used to check the resonant frequency of coils and circuits. Actually they aren't near as common as they were 20 years ago.

Hope that helps...you will probably get some more hints from others....Jay (KI7RH)

I don't see how you can avoid the problem of the lower SB mixing
with the upper SB of the 1st harmonic. Add em together and it looks
like a clipped audio signal - the AF harmonics mix. The only way round this
is to use side band (single) and/or very soft clipping.

If one clips SSB the harmonics reflect away from the base band rapidly
and the mixing products are removed by the very broad 2nd SSB filter
after the clipper.

No probs.

Murray Kelly vk4aok.

Source record: 108206

hello folks,

since some time I follow the discussion about baycom e.g. As I am a little competent about baycom let me drop a few words:

Regarding hardware:
Do you know about the existing baycom plug-in-card? It is call USCC (User-SCC, SCC stands for the Z8530 beeing used). The card has two SCCs, so four ports. One port is a AM7910 modem for HF/VHF, one a TCM3105 for VHF, a DF9IC style 9600bd FSK modem and a straight forward port. It completly adapts to baycom user software, to the baycom node and the baycom mailbox. There is also a RMNC/Flexnet following software called PC/Flexnet as baycom node will no longer be serviced. There is also a card available which has eight ports (four SCCs) but without modems.

Regarding software:
Baycom L2.EXE offers possibilities to transmit the AX.25 over many kinds of interfaces: Best known is the RS232 modem with the TCM3105. But there are many others: You can use the RS232 also as interface to a kiss server, e.g. TNC2. As mentioned above the USCC card. There is also a IPX interface which runs over a installed network, worth which transmission type (e.g. ARCNET or Ethernet, you just need IPX) I have a baycom mailbox running which provides also network services using Novell Netware Lite, as I use a L2.EXE which also
offers IPX support I can connect the mailbox via the network, too.

PC/Flexnet, which will soon replace baycom's L2.EXE, also offers the support for IPX as far as I currently know.

This is for your information. If you need more, please be shure to send a private copy for mee, too, as i do not always carefully watch the tcpip and packet radio groups.

There has been a thread here for a few days regarding SSB processing, vs DSB processing vs split band baseband processing.

It started me thinking about some products the Philips and others make called compandors (compression/expander like modem is modulator/demodulator). Does anyone know if these products do the kind of compression that we seek to do in the amateur service with RF kinds of things? I have never seen an amateur use of these devices that I can remember. The only thing close was the section in the 1985 Handbook on amplitude-compandored SSB.

Dave Covert was looking for schematics, etc. for a 12 VDC to 120VAC @1600 Watts inverter.

Dave:

I suggest that instead of building one, you should just buy one from either Damark or Crutchfield. I don't have either catalog at work today. Various manufacturers make models in power levels from 140 W up to 3000 W continuous duty. The 140W model is about $40 from Damark and the 1500W version is in the $400 to $500 range.

You could build your own, of course, but it would probably cost as much as the ones you buy. I know I couldn't build a 140W one for $40.

Call Damark @ (800)729-9000. They carry 4 models of inverters made by Recoton. They have a 140 watt unit ($40), a 300 watt unit ($80), a 600watt/1000 watt peak unit ($200), and a 1500 watt continuous/3000 watt peak unit ($450). You can drive a LOT of stuff with 3000 watts of peak power. You need VERY big cable to attach from the battery to the inverter. 3000 watts @ 12v is 265 Amps!

It is interesting to note that the reason these have gotten so inexpensive is that they are the principle ingredient in the megawatt car stereo amplifiers! That's the only way they can get the power from a 12V car battery.

I have recently acquired a box of tubes, all in cardboard boxes, many new, some used, as part of a bulk buy of other equipment. If anyone is looking to buy a tube, please send me an E-mail with the tube number and I'll check it against my list. If I have it, it's yours for $4.00 a tube plus shipping charges.

Not to take a cheap shot but couldn't the high number of responses be because the source was not printed? The authors have to be contacted to build the project. This would seem to be an indication of the number who DO want to program their own chips but couldn't because the source was not there!

Doug Faunt correctly caught my error in suggesting using "copyleft".
If I remember correctly the "copyleft" of the FSF allows for
commercial use, so the authors would have to morph it into a limited
use license of their copyright. This would allow unlimited personal
use, no commercial use, and require personal users to give back to the
group. Do y'all think this would work?

The electronic capacitance amplifier always works, but it doesn't excuse one from good electronic practice. It is not a substitute for RF bypassing. In fact, due to the finite gain-bandwidth product of the emitter follower stage, it is mainly a method to reduce *low frequency* ripple in a DC voltage. It does that quite well. Good practice tells us to use *both* a large capacitance and a small value capacitance to bypass 3 terminal regulators. The former for low frequency bypassing, and the latter for high frequency bypassing. The electronically amplified capacitor can allow us to use a physically smaller capacitor for the low frequency bypassing, but it doesn't free us from the need to also supply a high frequency bypass for stages prone to parasitic oscillation, like the above mentioned 3 terminal regulator.

>
>I am looking for schematics for a high amp DC/AC converter to use in
>the field.
>It should take 12VDC in and produce 120VAC 60Hz out at 1600 watts.

The device you are looking for is commonly called an *inverter*, and
is the major component of a *UPS*. Commercial versions are available
from a few watts up to the 100s of kilowatts.

However, 1600 watts from a 12 VDC source means switching over 130 amps.
Typically, inverters in the kilowatt range and larger are run from a
higher DC voltage, usually obtained by a series string of batteries.
An inverter for 1600 watts would typically operate off of 82 VDC.

>I realize the best way to do this is to have a design with a single
>'signal' card
>and multiple 'driver' cards. Each 'driver' card could procude 100W
>and take it's
>60Hz from a common source.

Well, not usually. The input DC is chopped, usually in the range
of 40 kHz to 100 kHz, stepped up in voltage by a toroidal transformer
to somewhere in the 200 to 400 volt range, rectified, and applied to
a Pulse Width Modulator (PWM) which feeds an integrating filter to
produce a stepped sinewave at 60 Hz.

This might be done in a modular fashion, but it usually isn't since
semiconductors capable of switching 1600 watts are readily available.
Commercial 1600 watt inverters go for around $100 to $200.

How did you 'check the cap' ? Were you able to determine that it would
hold a charge, or did you just check that it wasn't shorted ?

The most likely failure is that the cap is indeed open and will not take
a charge. That's always been the problem in the 3 or 4 that I've had die
on me over the years.

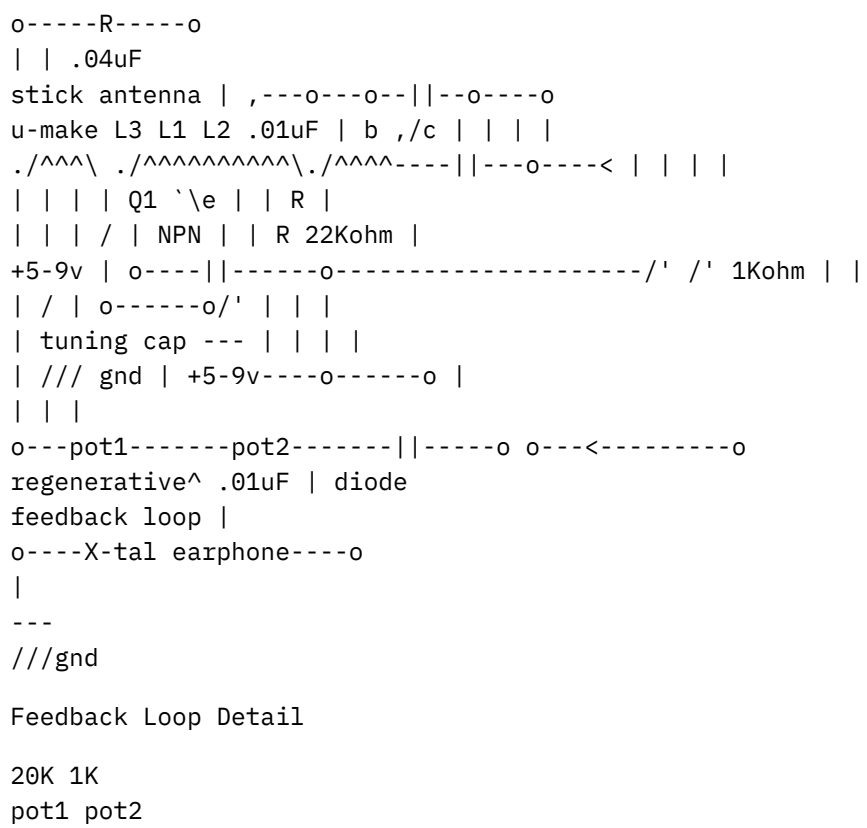
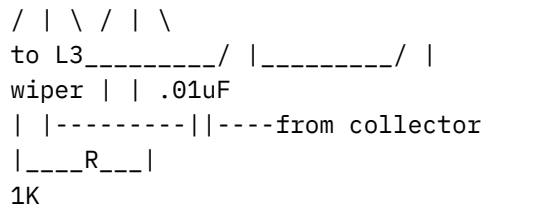
along this same line...
Here is a simple AM broadcast band, regenerative receiver. It
uses the stick antenna and the tuning capacitor from a junked AM
receiver.



Feedback Loop Detail

20K 1K
pot1 pot2



1. o ' ` . represent continuity, not components.

2. L1 and L2 are part of the stick antenna. There are 4 leads on the stick. The bigger coil goes across the tuning cap.

3. L3 is made by wrapping a strip of light cardboard around the ferrite stick and taping it. The idea is to have a short tube that you can slide back and forth a little bit on the ferrite stick. L3 is 4-7 turns of hookup wire wound on this tube, and taped in place. It makes a difference which way current flows here. If you aren't getting oscillations, you can slip this cardboard/coil/tape assembly off the stick, flip it end for end, and slip it back on.

4. The circuit should be built over a sheet of conductive material connected to gnd. This `ground plane' helps the stability/performance quite a bit. I'm not sure why, but it does.

Operation. The feedback control is very sensitive. Turn the coarse control (20K pot) very slowly and you should hear noise in the X-tal earphone. The noise only occurs at the point where the circuit starts to break into oscillation. You must be just below, (but very close to), this point to hear AM broadcasts. Feedback can also be controled by sliding L3 a little bit along the ferrite stick. When you find the point where oscillation starts back off a tiny tiny bit on the 20K, and sneak up on it with the fine control (1K pot). You have to operate the fine control pot with one hand, and the tuning cap with the other, to tune across the band. Lower frequencies need less feedback.

If you can't get a noise in the earphone:
1. L3 is backwards. Turn it around
2. There is too much feedback even with pot 1 adjusted for max R. Remove turns from L3
I'm a beginning DIY electronics student, and not a ham, but I had a lot of fun and learned a lot from this circuit when I started trying to teach myself this stuff at almost 40 :).

Yes, you can. Use 0.7 volts as the approximate drop across each diode
for purposes of calculating the total drop.

>How consisent is the forward drop of a particular line of switching
>diodes from batch to batch?

I've found the forward drop within a given family of diodes to be very
consistent. For the use you've described, I think any variation will
be insignificant.

Incidentally, I used this technique once in a high current homebrew
power supply. I only had a handful of fixed 12V regulators and
several pass transistors to work with. Basically, I used the
forward-biased diodes to "float" the ground pin of the regulator, in
order to increase its output voltage. I used three 1A power supply
diodes diodes, and by hand selecting the regulator IC's, I was able to
find one that provided exactly 14.5V output. When I used this to drive
the parallel pass transistors, their 0.7 base-emitter drop resulted in
exactly 13.8V. :)

I've been working on the AT-11 project as well. I'm sure I'm going to more trouble than its worth, but I trying to model the thing on a standard PC using C++. I was hoping to experiment with different tuning algorithyms etc. I intend to design an algorithym thats fast and uses the fewest number of relay clicks.

The focus of my project at this point is writing a program to draw a smith chart and plot impeadance points as I run my algorithym. The smith chart is a handy way of looking at impeadance data - although it has slowed me down quite a bit. I have already written the functions needed to model different algorithyms - just need to write the algorithyms.

I am also looking for a schematic for a "phase / mag" detector - to use instead of the directional voltmeter (or what-chu-ma-call-it) used in the QST project. That way the program could predict the best match instead of clattering relays looking for a match.

I would like to see other folks post info on this here if they get involved with the project. I'd be happy to trade info, but not give it away freely.

312. FS: Vhf High Power Duplexer

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-13 00:00:00 UTC
From: "{Gary} KF9CM turtle"@wwa.com
Message-ID: <4d74h9$gsp@kirin.wwa.com>
Source record: 108130

I have for sale a Sinclair 4 cavity high power VHF duplexer Model# Q-202GC. To my knowledge it's never been used. The cavities are inclosed in a steel cabnet with (3) three conectors on the side. The frequency tuning range is from 132 to 174 Mhz and I have the complete tuning manual.

The Electrical Specifications are as follows:

INSERTION LOSS= Tx 1.5 db
Rx 1.5 db
ISOLATION, Tx Noise at Rx frequency = 80 db
Tx Frequency at Rx Terminal = 80db

MINIMUM ISOLATION Between Tx and Rx Frequencies = 50db

MINIMUM SEPARATION = 500Khz

This is a top of the line duplexer and lists from Sinclair for $1730.... I will take $850 or best offer. This is for local pickup or I can deliver within a 100 mile radius of Chicago Il.

You can "E" mail me at turtle@wwa.com

Included in my very careful analysis caveat is the effect of
additional capacitance on the emitter of the
emitter-follower.

Some other thoughts on the "If some are good, more are
better" bypassing schemes. One should also consider that
most "low-frequency" capacitor types have fairly low
self-resonant frequencies (SRFs). Above SRF, the capacitor
looks inductive. If this "inductor" is shunted with the
appropriate value "high-frequency" bypass, it is possible to
get a nice high impedance parallel tuned circuit right where
you want the exact opposite. Sprinkle in a few more caps
and you can have even more fun. For instance:

Some years ago, I was approached by a new college grad who
was trying to solve a problem with crosstalk in an i-f
amplifier used in a monopulse radar. This consisted of three
amplitude and phase-matched amplifiers that used matched
everything; FET amplifiers, PIN diodes for AGC and matched
Schottky diode bridges for blanking. Each amplifier board
was installed in a fully shielded machined housing with
feed-thru caps on each power supply and AGC lead. The wires

to these caps were daisy-chained from one to the next. The problem was that despite all the precautions, there was inadequate isolation between channels and poor AGC tracking. Weeks were spent looking at device matching, grounding, etc.

I suggested to this young man that he locate a grid dip meter and look for resonances in the decoupling circuit. (His response was, "What's a grid dip meter", but that's another story). Sure enough, there was a resonance between the connecting lead lengths and the capacitors close to the i-f. A change in wire dress and feed-thru capacitor values moved the frequency enough to eleminate the problem. Here was a case where everything was done "right" and we still had a problem.

>Handbook on amplitude-compandored SSB.

Compressors are different from the clippers in purpose. A compressor
is an AGC amplifier that responds to *average* speech level using a
relatively slow time constant. Clipping is designed to remove momentary
voice peaks so that the peak to average ratio of speech is reduced.
This latter is important because it relaxes the constraints on the
linear amplifiers since they don't need such a high linear peak power
response. A compressor's time constant is much too slow to follow peaks,
so it doesn't relax the peak to average ratio constraint on the linear
amplifier, though it does increase the average demand on the amplifier.
The two circuits are typically used *together* to increase "talk power".

Sure, you bet, the non-obvious can bite you if you aren't
careful. That doesn't detract from the value of the
capacitance multiplier technique in general, however.
It just means you have to use it in conjunction with
the care you'd use with any other method.

Since we're into war stories, I'll relate a recent incident
which may highlight overlooking the obvious. I was called
in to aid the chief engineer of a local television station
with a problem he was having at his transmitter site. The
symptom was very low chroma on the transmitted signal. He
had swept the transmitter, and its response was fine. He
had checked the output of the STL, it was fine. He had
bypassed all the terminal equipment between the microwave
and the transmitter, no help. He was stumped.

I took one look and immediately saw the problem. The cable
carrying the signal from the STL to the transmitter was
roughly 1/4-wave at 3.58 MHz. Obviously it was acting as a
suck-out trap. The only way that could happen would be for
a ground to be broken. Sure enough, in the STL frame, the
ground trace to the BNC was cracked. Thanks to good plant
grounding, no hum was introduced that would have given
the problem away, but the coax was acting as a trap for
the 3.58. A moment's work with a butane soldering iron,
and the suck-out magically disappeared. Case closed,
collect fee. :-)

I seem to remeber a few posts a while back about being able to tune in SSB stations with an AM radio (SW) by just running a 477 khz oscillator near it.... Is this true? Do crystals run down that low? If so I could just build a VXO in that area and be able to adjust it... Has anyone made this work?

>
>Gary

Hi Gary,

I don't think I analyzed it wrong.

The rise time of the transformer actually helps prevent the coupling of high frequency transients to the secondary (at least in the designs I am familiar with) much better than a MOV ever could. You aren't trying to say a typical 60 HZ transformer requires time to saturate, and responds very well to transients?

Most transformers I'm aware of are operated *reasonably* close to core saturation. If they are not operated that way, efficiency, regulation, and space is wasted. No manufacturer likes to do that. Core saturation makes it virtually impossible to couple transients to the secondary through magnetic coupling. If the transient is large enough to do damage, the MOV would likely be useless anyway since it's shunt resistance is so high compared to the saturated winding impedance.

The on resistance between 6 and 20 ohms is about worthless across a power line, unless the transient is pretty puny or comes from a high impedance source. If the transcient is that frail, the transformer can handle it fine. If the transient comes from a "stiff" or low impedance (high current) source, the MOV has too high an impedance. The equipment is history anyway!

I'm not saying MOV's are usless in all applications. They are great in some applications, such as telephone lines (where the goal is to protect the customer or house). They can certainly help protect line operated transformerless supplies, and can reduce the chance of arcing from extremely high common mode voltages between the line and chassis. MOV's just don't do much to help things on the secondary side of a transformer. A six ohm clamp isn't what I would consider particularly "hard" compared to the impedance of a 20 amp 120 volt supply line.

The usual i-f is 455 KHz. Yes crystals can be had for this frequency. A vcxo would probably have very limited tuning range, however. This scheme will work after a fashion. The AM detector is used to mix the externally supplied carrier (BFO) with the SSB signal. The problems include; getting the BFO to i-f amplitude ratio correct, AGC system overload from the BFO, poor i-f selectivity, etc.

Good luck.

Source record: 108141

Hello
Have anyboby good tips for cnnecting transverter to
Kenwood TS-440SAT. My transverter is from 28MHz to 50MHz.
The TX-converted needs abt. 0dBm signal and my plan
was to take that 28MHz rf-signal before final unit.
Another way is take signal from antenna-connector.
Then i must reduce output power of final unit by using
alc-voltage, but theres possibility for damage if my
alc-connector poorly connected: 100w to transverter input ==
big cloud of beautiful blue smoke.
It is also possible to run power to the dummy load and
take signal from it by attenuator, but i dont want to
warm up my hamschack.

If i take power before final unit, then i must somehow
"kill" final unit or cut off the signalway from
driver to final. If only i cut signal, is it possible that
the final start to oscillate on its own?

In ICOM IC-735 is connector for transverter, but i dont
know how it is done in that rig.

Jukka/OH*NLP (* = 0 - 9, normally 3)(1996 pxf also could be OI)

> kHz aspect ???)

The cans are the IF transformers, and maybe a shielded coil or two
as well. The way to tell the difference is that the transformers
have two isolated windings, the shielded coils do not. (The shielded
coils may be oscillator coils.) The screwdriver like slot tunes the
core of the transformer. Note: don't use a real screwdriver, a non-
metallic tuning wand is required (a set of them is available from
your local electronics supplier). You can easily break the ferrite
core material with a regular screwdriver, and the metal of the
screwdriver will detune the circuit, making it difficult to adjust.

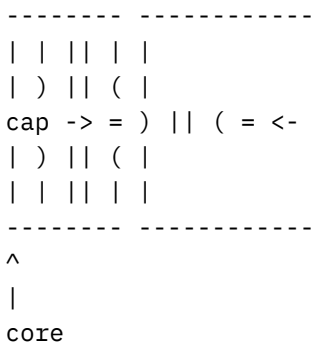
> to get me to do. How would I use a receiver to do this? What is a GDO?
> What is "zero-beats"?

Ok, the transformers have internal capacitors in parallel with the
windings. The schematic looks like this:



As you can see, an IF transformer consists of two parallel resonant LC tanks coupled together by mutual inductance. By screwing the core in or out of the coils, the *inductance* of the coils is changed. That in turn changes the resonant frequency of the LC combinations on the primary and secondary. If you remember from your exam, ferromagnetic material changes the inductance of a coil, increasing it when present, decreasing it when absent. So screwing the core *in* increases inductance while screwing it *out* decreases inductance. That, of course has an inverse effect on frequency of resonance, IE screwing the core *out* increases resonant frequency while screwing it *in* decreases resonant frequency. So that's how you "tune" the transformer.

Ok, what's a GDO. GDO stands for Grid Dip Oscillator. Now we don't use vacuum tubes much anymore, but the term has held on. What it is is a test instrument consisting of a tunable oscillator with an exposed coil. That coil is brought near something whose resonant frequency you want to find. When the GDO is tuned to the resonant frequency of the unknown, energy is drawn out of the oscillator coil, and a "dip" in current is seen on the meter, which is measuring feedback current in the "grid" (or gate with a modern FET) of the oscillator. That's very useful. Amplifier tank circuits can be pretuned using a GDO, and antenna resonance can be found using a GDO.

With a powered oscillator circuit, there is another way. That's to use your receiver to find the frequency of oscillation, which will, of course, be the resonant frequency of the unknown LC tank. Now with an SSB receiver, as you tune near a signal, you hear a beat, or tone, in the receiver. This is a mixer product and corresponds to the *difference* in frequency of the receiver oscillator and the unknown oscillator. As you tune closer to the unknown oscillator's frequency, the beat note will become lower in pitch. Finally, when the receiver is exactly tuned to the oscillator's frequency, the difference will become zero, and the pitch of the beat note will become zero, IE zero beat.

It's been a long time but one of my electronics instructors in school once did a lot of his own research on power conditioning techniques. Using a transient generator and scope, he had good luck using MOV's if they were across all three inputs (line, neutral, and ground) and preferably followed by a low-pass filter network. The LPF helped "slow down" the pulse while the MOV went into conduction. All of this preceded the transformer primary.

By the way, semiconductor devices such as "Transorbs" are much faster but are also less robust and more expensive.

I believe Phil Karn has just this sort of protection on the KA9Q
package. It's a much more vulnerable product, and I don't know how
it's working for him.

The more I learn about the 68HC11, the more frustrated I am about
this. As near as I can figure, the antenna tuner could be its own
developement system, with the addition of a pair of RS-232 converters,
and software to run on a PC or Mac that's available as freeware.
No EPROM programmer or eraser required.
I'm still learning. I've been getting packages from Motorola on a
daily basis, although that's slowing down.

>just don't do much to help things on the secondary side of a transformer.
>A six ohm clamp isn't what I would consider particularly "hard" compared
>to the impedance of a 20 amp 120 volt supply line.

You didn't read what I wrote, Tom. During the IEEE 8/20 transient,
the MOV has an effective "on" resistance of 6.15e-6 ohm, that's
not 6 ohms, that's 6 *millionths* of an ohm. This is dynamic
behavior, of course, and only lasts for the 20 microseconds of
the transient waveform. If the transient persists, steady state
"on" resistance is around 20 ohms, but the device will self-
destruct under that condition.

MOVs certainly do work to protect transformer powered equipment,
as the blown MOVs in my Astron supply attest. They gave their
lives clamping the lightning transient, and the power supply
survived. On reflection, MOVs of greater than 60 joule surge
rating should have been in there. They wouldn't have died while
doing their duty.

You might think that the transformer would swallow the transient,
but it won't. The core saturation has nothing to do with it. The
transient will couple through the transformer via the inter-winding
capacitance and puncture electrolytic capacitor junctions and
solid state device junctions if the MOV is not present. The transient
is very high frequency RF.

A MOV can't be modeled as just a voltage dependent resistor. Its
dynamic behavior is much more complex than that. It's made up of
a sintered mix of electron donor and electron receptor materials.
The 60 joule device for which I quoted specs has the ability to
"eat" 3/4 of a coulomb of charge, and leak it away gradually

and safely after the event. The best model for a MOV is that of
a paralleled RC snubber, but that doesn't accurately portray the
complete device physics either. Once the charge is "swallowed"
it can't get out either way without going through the high "off"
resistance of the device.

Let me try a crude description of how a MOV works. Inside the
MOV, picture a bunch of capacitor plates separated by insulating
material. Initially, the "capacitors" have a neutral charge, and
the insulation value is high enough to prevent sensible current
flow. During a transient, the insulation breaks down, a non-destructive
(if within device joule ratings) arc forms which rapidly charges
the capacitor plates. This distributes charge throughout the device.
The potential between one "capacitor" and another is small enough
that the insulation doesn't break down, and the current can't get
back out except by very slow leakage. It "eats" charge, up to
3/4 coulomb of it for the device I described. It can't do that
indefinitely, of course, which is why it can only handle a transient
of limited duration. Longer duration overvoltages will make the
insulation arcing destructive rather than non-destructive and
the device becomes conductive and destroys itself.

333. Publishing Articles

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-13 00:00:00 UTC
From: web40@charweb.ORG
Message-ID: <Pine.SOL.3.91.960113122140.9134B-100000@wilbur>
Source record: 108151

I have been reading with interest the discussion of publishing articles in magazines such as QST, etc. In my opinion, as long as a construction project has a broad appeal, contains parts which are available at a *reasonable* price, (No specialty parts which are selling for an outrageous price as compared to similar parts), and is not just a redesign of an earlier item unless it introduces a new technology or idea, then I would welcome seeing it published.
As far as the use of specialized parts in a construction project, I disagree with the idea of saying "if you want it to work, buy XXX part." Amateurs have a long tradition of homebrewing workarounds for parts which for one reason or another are hard to come by. For that reason, enough information *should* be provided in the article to build a working model by using ingenuity and other available parts if the builder wishes to do so. (IMHO a homebrew project should be just that. If you can come up with a different way of obtaining the results, more power to you!) I have no problems with an article that offers parts/kits/circuit boards, etc. to use *if you don't want to build/design your own*, however for publication in a section dedicated to homebrew type articles, it shouldn't be "required".

Its possible the tube is bad - However are you sure the trigger is
operating - the you might see if you can draw an arc from the trigger
transformer (4kV) if you trigger the flash.

Replacement tubes are usually available - but not cheap. In the US
Mouser Electronics sells them...

Also you might want to list on the rec.photo.misc ----- or other photo
groups

Newsgroups: rec.radio.amateur.homebrew
From: ke3mf@atc.ameritel.net (Glenn Thorn)
Date: Sun, 14 Jan 1996 07:43:39 GMT

The authors of the autotuner were a bit concerned since they didn't
want 2 years of work to be stolen by another company and their code
put to use in another "like product".
I'm not convinced this fear is realistic, but it is apparently there.
Once again, I refer to the KA9Q code, and the protections it has.
I'd also be willing to sign a non-commercial use agreement, myself,
but that doesn't affect the education of the general ham population
issue.

A few other points:

- The code is of no use to 90 percent of those who build the tuner,
Assembly is not easy to sit down and understand.
It's not that hard, either. And there are a lot of us who've done
some of this at various times. The architecture of the 6800 is not
complicated, and if there's a framework to build on, it's even easier.
And, refering back to the KA9Q example, many people
have contributed to that effort to the benefit of the whole community.
But should the article be aimed at only those who build the tuner?
How about those who would be able to learn from the article how such a
thing is done?

- You must have some way to burn the chip, the tuner doesn't have
RS-232 capibility.
Once again, adding this is not hard. I actually want to be able to
control the tuner via RS-232, so it's got double usage. Software for
this is freely available. I suspect that most of us who would make
changes would have to replace the A1 version (512 bytes of EEPROM) of
the uprocessor with the 8E2 (2048 bytes) version, to have some working
room. This is the big expense.

- Dwayne will release the code for an SASE and a disk, call him!
Now this seems to be a new offer, that I plan to take up.

- The ARRL did not print the flow chart of the software, that was
their choice. (My quess is it wouldn't mean much to the majority of
the readers)
I've already sent a SASE for the flowchart.

I asked Dwayne to give me the .s19 file for posting here. It is the
Hex dump to the chip so if you have a burner, you can upload it to the
chip if you want to purchase it or already have one. I think he will

do it, please post or E-mail if you want it (free, of course).

In case anyone cares, I did the initial relay testing and final
product testing... for no compensation.
Thnak you very much for this. This is one of the parts of the unit
that makes it a worthwhile article as it is, and such a shame that it
stopped when it did.

Great comments, everyone!

I have a lot of mixed emotions on this. It *is* 1996 and ICs are the way electronics are built today. I'd like to see more use of high-function ICs in home-build articles. On the other hand, it *is* 1996 and a lot of us make our living doing software. I view these articles as something to learn from. I was unhappy that there wasn't at least a flow chart. My guess is radio electronics may not mean much to a large portion of QST's readership - that's not the best excuse. The idea is to teach something.

I like the idea of being able to get all the parts somewhere and get the parts that are tough to do at home (like the programmed IC). But, ever curious, I would like to know how it works.

>tried this URL and it goes nowhere. Does anyone have another source for
>this software?

Back out a little, Carter, and it works, IE try
http://users.aol.com/spoulsen/ and you'll get the
home page. Click in the download section and you'll
get the zip file. Apparently there is no index.htm
on the server, and that's what's causing the problem.
Note, there seems to be a missing gif on the homepage
as well, ignore that too. Just go for the goodies.

The zip contains a crippled version of the software,
you've got to register it to get it to save and print,
but the price is right.

>The authors of the autotuner were a bit concerned since they didn't
>want 2 years of work to be stolen by another company and their code
>put to use in another "like product".

I have no problem with this but it does shoe that the author considers
the unit a product. The historical purpose of publishing an article in
a technical journal has been to share information. If he wants to
consider it a product great and I hope he make a return that
encourages him to keep producing products for the amateur market.
However why should this type of product be given space in a journal of
the ARRL. Ten Tech has an intresting new line of kits, shoule they be
payed to partially describe thier offerings in QST?

Its not the manfactures of the product I have a problem its the
editors of QST that I disagree with. The articl is no more than a
product review. And its reviewed by the same firm that sells it. Not
avery suitable arangement.

>A few other points:

>- The code is of no use to 90 percent of those who build the tuner,
>Assembly is not easy to sit down and understand.
Well written assembly is no tougher to understand than any other techinical presentation. Properly commented you don't even to know the code of the specific processor to "Understand" the operation of the program. ANd isn't that selling the members a little short saying we aren't able to understand?
>- You must have some way to burn the chip, the tuner doesn't have
>RS-232 capibility.

>- Dwayne will release the code for an SASE and a disk, call him!
But in the future any one reading the article won't know that. In the future people researching the progect won't know this. I still go back to articles published in the 60's to understand phasing type SSB generators. And that is only one example.
>The ARRL did not print the flow chart of the software, that was
>their choice. (My quess is it wouldn't mean much to the majority of
>the readers)

My guess is that many explanations go over the heads of many readers, however I don't see that as a reason to ignore those that could understand. And those that don't understand are the ones that could benifit the most if they studied it.

>I asked Dwayne to give me the .s19 file for posting here. It is the

Well I'd rather have his flow chart posted. Do you think he would let you do that?

>In case anyone cares, I did the initial relay testing and final
>product testing... for no compensation.

And I thank you.

>Great comments, everyone!

>73,

>de Glenn, KE3MF

As you know the author please pass on to him that I think he has an interesting product and it seems very fairly priced. Do you know why the decession was made not to use a phase detector? As 4 A/d were available it would seem to have been a natural and made the algorithem even simpler. (of course I haven't any effort in either type of program>)

However even though myself and others have commented on the lack of a phase detector everyone should remimber that probablly 99 percent of all who use a manual tunner. use a SWR bridge only. And if you can do

it manually then properly written code can do it.

>> You have gained nothing with a multiband clipper.
>
>With your example, we can't call it a clipper because you specified no
>clipping is occurring. Obviously, there is nothing gained until we *do* allow
>clipping. That's what it's all about.

Allowing clipping does not change the situation.
If we set the clipping at +/- 1/2 the peak amplitude in each channel,
we get square waves with half the amplitude of the pure tones (f and 2 f).
Bandlimiting the channels, the harmonics of the square wave are filtered
out and we get sine waves at 1/2 the original amplitude. Summing these
signals, we get the original signal envelope which is attenuated by 6 dB.
Since the envolope is still the same, there is not an improvement in
peak-to-average ratio compared to the case of no clipping.

I admit that assuming that the f and 2f tones of the original signal are
a bit unrealistic. For typical voice signals the harmonics are weaker
and the high frequency channels will not limit as easily as the low
frequency channels. The net effect is a change in the spectral contents
of the signal favoring the high frequencies.

This is just a high-pass filter with the corner frequency controlled
by the signal level :-)

While it is interesting to debate the peak-to-average, readability is a
much more complex subject. Other factors, such as the quality of the voice
(male/female) the spectrum of the noise+interference at the receiving
site affect the readability.

<< The authors of the autotuner were a bit concerned since they didn't want 2 years of work to be stolen by another company and their code out to use in another "like product". >>

That statement indicates data was withheld just to protect "two years of work" that went into the software.

So which reason was it really? Was data accidently left out by QST as a mere oversight or space saving gesture, or did the author request it be left out as a favor to protect "two years" of work?

This is begining to sound like someone danced around the truth a bit in the earlier replies.

Tom

As you know, I agree with QST's decision to publish articles such as this. It's also my opinion that most of the objections have either been the result of a subjective (emotional) response or are based on a flawed analogy. Few valid points have been made against this specific article or the specific, proprietary part it requires.

That said, I do have a concern for articles like this, namely the possibility that the part will be unavailable in two or three years. Unlike an obsolete tube or IC, there may be no commonly-available substitution, and this in itself undermines the value of the article. In effect, the article's "shelf-life" is determined by the length of time the author is willing and/or able to provide the part, and anyone whishing to duplicate it a few years after publication may be out of luck.

In addition, given that the authors of such articles are not (in most cases) commercial entities with an established history of product availability, there is significant risk to anyone who undertakes the project. Should the proprietary part later fail and a replacement be unavailable, the equipment becomes useless.

To circumvent this situation, perhaps QST should refuse to publish articles if the author is unwilling to provide the source code to ARRL for safekeeping. Even if the software is copyrighted, the author could give permission to distribute copies at some point in the future. Perhaps the exact time could be determined on the basis of the availability of the programmed part (or a functionally-identical equivalent) directly from the author. A clause could also be inserted that requires the price to remain at the same level as when the part was originally offered, excepting only increases in hardware (IC) costs to the author.

Such an arrangement between author and publisher would go a long ways towards protecting the intrinsic value of the article, as well as the investment of those who construct the project.

My apologies if the preceding points have already been made; I missed a few of the posts recently.

>be able to adjust it... Has anyone made this work?

You *can* do this, though actually since the IF is 455 kHz, you'd want your oscillator to operate on either 453 or 457 kHz depending on whether you wanted to receive USB or LSB. There are serious problems with this approach, however. The AM set uses an *envelope* detector while a true SSB receiver will use a *product* detector. With an envelope detector, you have to be *very* careful to have just the right carrier reinsertion amplitude or severe distortion will result. Since the required carrier amplitude varies with the signal strength of the signals received, you need some way to continuously vary this, and that's neither simple nor easy.

A much better approach is to build a product detector and go in and add it to the AM receiver in place of the envelope detector (a switch could be used to select the proper detector depending on whether you want to receive AM or SSB). A product detector is not a complex circuit, and can be built up on a small board that can be tucked inside the radio.

Elantec are advertising the EL4083C current-mode 4-quadrant multiplier which goes up to 200 MHz. It's in an 8-pin DIL package and looks quite easy to use. It should nake a good substitute for the Motorola devices. Samples are available from Elantec on (800) 333-6314 ext 311.

I think that the NE602 has been replaced by the NE612.

The authors of the autotuner were a bit concerned since they didn't
want 2 years of work to be stolen by another company and their code
put to use in another "like product".

A few other points:

- The code is of no use to 90 percent of those who build the tuner,
Assembly is not easy to sit down and understand.

- You must have some way to burn the chip, the tuner doesn't have
RS-232 capibility.

- Dwayne will release the code for an SASE and a disk, call him!

- The ARRL did not print the flow chart of the software, that was
their choice. (My quess is it wouldn't mean much to the majority of
the readers)

I asked Dwayne to give me the .s19 file for posting here. It is the
Hex dump to the chip so if you have a burner, you can upload it to the

chip if you want to purchase it or already have one. I think he will do it, please post or E-mail if you want it (free, of course).

In case anyone cares, I did the initial relay testing and final product testing... for no compensation.

Great comments, everyone!

No, what we get is a signal that has all the levels at different
frequencies limited at the same threshold, exactly what we try to do in
any processor!

The result is instantaneous "compression" or limiting of each frequency
sub-band to a predetermined level. It can then be re-mixed at the level we
desire without the addition of unwanted intermodulation products or
harmonics of the original input. We have simply removed all amplitude
variations in individual sub-bands and re-combined them at the ratios that
improve communications without adding unwanted byproducts.

The improvement is very real on speech, but not on a two tone test.

I've had trouble with the trigger transformer in several (cheap) flash units.
Tthe transformer is supposed to develop an 1-2 kv pulse. I think the failure
mode is an internal short (probably between layers of the secondary).

A cheap (often free) replacement can be had from your local color print
processor. Those throw-away cameras have complete flash units. Often, you
can get a couple of cameras just for the asking. The trigger transformer is
easy to identify.

355. 10ghz Audio link

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-14 00:00:00 UTC
From: n0nas@hamlink.mn.org
Message-ID: <821642510.AA04980@hamlink.mn.org>
Source record: 108172

The basic method of using a 10 GHz motion detector or Gunnplexor for a full duplex audio link is quite simple. All you really do is set up the first Gunnplexor in the ham band and apply a small amount of audio to the voltage regulator feeding the Gunn diode. This causes the 10 GHz oscillator to be frequency modulated by the audio signal. Now at the other end, you connect a wideband receiver to the detector diode of the other Gunnplexor and tune the second Gunn oscillator to be higher or lower in frequency by whatever the receiver frequency is. For amateur 10 GHz voice, this is usually 30 MHz and about 75 KHz bandwidth. This is 1/2 of the full duplex link. To go back the other way you voice modulate the second Gunn oscillator and add another wideband FM receiver at the same 30 MHz receive offset to the detector diode of the first Gunn unit. You finish off the link by generating an AFC output from one receiver to adjust the static regulated voltage on its Gunn oscillator. Then, whenever the first unit drifts in frequency, the second unit will follow always keeping 30 MHz away. NOTE: there is nothing hard and fast about the IF frequency you use, just that ALL the stations must use the same IF in order to communicate.

The limitations on this technique are primarily the low power from the Gunn oscillators, their wide frequency variation with temperature, and poor range due in part to the wideband FM modulation. Various articles have suggested anything up to 200 mile range using SSB and 50 to 100 mw with a dish on 10 GHz. The FM voice system would do well to get 10 miles with a 10 mw motion detector transmitter. The ARRL article will basically do the voice link if you drop the data specific stuff. If you want more info on using Gunnplexors and motion detectors for 10 GHz, the most recent info will be in the "Above and Beyond" column in 73 magazine during the last 5 years. And before that there were numerous articles about 10 GHz in Ham Radio and 73 Magazine in the 1980's.

When you go looking for equipment, the best parts to find are the Microwave Associates Gunnplexor units. They were designed for communications and have a modulator diode along with the usual oscillator and detector diodes. This makes them more stable and easier to modulate but they generally sell for over $200. The cheap option is an old microwave motion detector from an alarm system. The 10 GHz section is an aluminum block about 1.2" by 1.8" by 2.5" with a feedhorn or square flange on one end. These only have the oscillator diode and detector diode. Modulation must be floated on the static operating voltage of the oscillator diode. They usually run about 10 mw output and cost under $25. Whatever model you choose it should have a standard waveguide flange so you can connect to different horns or mount it in front of a parabolic dish for maximum range. If you are really just playing around, some old X-band radar detectors can be stripped

sometimes for this type of project but strictly as a backyard receiver project.

I did some brain storming about this a few years ago. You might want to look for some old surplus low band FM receivers in the 30-40 MHz band. Many of them have wideband (30 KHz) IFs and all have excellent sensitivity. Every pair you find on one frequency can be another link. Lets say you find receiver pairs for 31, 32, 33, and 34 MHz. Build one site as the central site with four receivers and four separate remote sites each with one receiver. The remote sites are each tuned slightly different from the central site and is AGCed to lock to the central site. At the central site, add a low noise preamp to split the signal for all four receivers and you should have four working remote receiver voice links. I always thought this would be a cute repeater receiver linking system but never took it anywhere.

Have fun with 10 GHZ. 73's.

With any transformer-input circuit (many pro balanced ins still use transformers), you should indeed ground one side of the balanced line, and feed your unbalanced hot side to the other balanced pin. Usually for microphones, the phasing standard is "pin 2 high, pin 3 low".

Surprisingly, you may not actually have a balanced input even with XLR connectors -- I have a Yamaha board at work like this where the balanced transformers are an *option*, and not installed.

If it's NOT a transformer input, you should do what gives you best results: just feed from ground to one of the balanced legs. In this case, there's an active differential input, and grounding one side will do you no good in some cases.

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

360. Circut req'd - telephone line in use indicator.

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-15 00:00:00 UTC
From: ai657@freenet.toronto.on.ca
Message-ID: <DL8H7r.29r.0.sheppard@torfree.net>
Source record: 108078

I know it is a litle off topic but here goes. I need a circut diagram for a
"telephone line in use indicator". We have three modems on a single
telephone line here
and we are constantly cutting each other off. I guess it would have an
LED to indicate
line usage and would be plugged into the phone jack of our modems. I have
heard that
manufactured units exist but can't seem to find them here in Toronto.
Any help would be most appreciated.
Please e-mail. Thanks.

Mystery solved: While perusing ATV Quarterly, I saw a couple of notes on
power amps. The network in question is used to suppress low frequency
oscillation.

>justified benefits.

The IEEE 820/20 waveform looks like a 2 uS sinc^2 pulse with an asymtotic
decay tail over 20 uS. The pulse rises at 1 kV/nS for 1 uS, so it peaks
at 1 Megavolt (no load). Of course depending on the energy of the pulse
in joules, and the shunt impedance, it won't necessarily make it to 1 MV
into a load. This pulse is designed to mimic a nuclear EMP. The IEEE 587
pulse is designed to mimic a lightning surge transient and has a somewhat
slower risetime and a negative "ringing" component at 80% of peak positive
amplitude following the initial 2 uS sinc^2 pulse, and trails off in
typical damped wave fashion over a longer interval. The IEEE 820/20 pulse
is the more stringent test, and is what's typically used to qualify surge
suppressors. If the suppressor can handle it, the IEEE 587 pulse should
be child's play (but that's not always true, that negative "ringing"
component can stymie some suppressors).

And, there's yet another IEEE pulse shape, the IEEE 8/20 pulse, which
has a 8 uS rise and a 20 uS decay in essentially a triangular form.
(I may have inadvertently mixed this up with the IEEE 820/20 pulse
in an earlier post.) This pulse may be seen downstream of certain
types of transformers or entrance networks. Typically it will have
a peak voltage of only 6 kV, but will have essentially the same energy
as the IEEE 587 pulse.

>Without MOV's in equipment, and only using simple low pass filters (that
>also function as RFI filters), I have never seen a transient induced
>rectifier or component transient induced failure. But then all of my line
>operated equipment designs use transformers. I'm sure if they were line

>operated switching supplies a zener or MOV clamp would be a worthwhile
>addition.

I can show you the power supply choke out of a Harris 100 kW TV transmitter
that's charcoal thanks to a lightning transient that jumped the insulation
and established an ionized path. The bulk of the damage was done by stepped
up line current, of course, following the path established by the transient,
but the transient was the "ignition" source. If there had been adequate
suppression on the 480 line, the transient would never have been high
enough to start the ionization path that led to the failure.

Now you're probably right that a lowpass filter would have snubbed
the peak voltage, but it wouldn't have damped the energy at all,
just spread it out into a "ringing" voltage at the lowpass cutoff.
As I'm sure you know, that can have unexpected and undesired
results in a high energy circuit too.

>>The steady state "on" resistance is around 20 ohms, but if the overload

>only danger is the common mode voltage causing the transformer to arc, but
>the line bypasses and terminal strips would fail first.

As I noted, core saturation plays no part with 1 kV/nS pulses. They
capacitively couple between the transformer windings, unless you
use a ferroresonant or Faraday shielded transformer of course. Note
that's *nanosecond* not *millisecond*. Transients almost by definition
are *very* fast pulses. They usually don't pack a lot of energy (which
is good or little bitty MOVs would be of no value), and don't do the
damage themselves in line operated equipment. What they do is serve as
junction puncturers or "ignition" sources. It's the ordinary line current
that then does the damage by following the path created by the transient.

>I'm not familiar with Transorbs, but I am always looking for ways to
>improve protection of high power transformer-operated equipment. Who is
>the manufacturer of transorbs?

Transorbs are silicon devices, think of them as *very* fast zeners. An ordinary zener doesn't have nearly fast enough response to be of any use for transient suppression (turn on is typically in the 40 uS range, the transient is gone by then). Transorb is someone's trademark name (I don't recall whose at the moment). You'll find generic examples of these devices in the 1N62XX number range. For example, the 1N6296A is a 110 working volt protector with a 10A surge rating (1.5 joule), and a turn on threshold of 152 volts. Turn on is in the 400-500 *picosecond* range. (Fast buggers.)

Transorbs have the fastest response, MOVs are next, and gas tubes last. But the order of robustness and energy handling is the reverse. Gas tubes can handle surge of very high energy while MOVs and Transorbs can handle much less. For very very high energy surge, silicon carbide suppressors can handle the most, but they are one-shot devices and self-destruct (explosively, it's quite a sight) when they protect. They're the best thing to use right at the facility entrance (and the cheapest too). For most transients, they won't fire, and you still need gas tubes, MOVs, or Transorbs downstream, but if the granddaddy direct strike occurs, the silicon carbide protector will fire, and probably save your plant.

I believe the magazine is called "Nuts and Volts", not "Nuts and Bolts"
It's basicallly a classified ad magazine with a bunch of technical articles
in it. I get it once in a while myself. The articles are usually pretty good.
They have "build it yourself" as well as the "look what we did" articles.
This month I read one about radio controlled robots. One key feature is that
if you are looking for a piece of ham equipment, then someone in the classifieds
is selling it.

>Not sure of Z in ckt.

Balanced XLR *is* standard, it's those funny phone jacks that are
non-standard. :-)

For microphone level (-55 dbm), the impedance is 150 ohms. For line
level (used to be +8 dbm but the industry is switching to +4 dbm)
the impedance is 600 ohms.

You don't want to destroy the system balance by grounding one of
the pair. You'll have hum pickup and other nasties. Standard
transformer adaptors are available, XLR on one end, transformer
in the middle, and 1/4 inch phone plug on the other. (Or sexed
vice versa for use on the other end of the line.)

If you're going into a high impedance unbalanced input, there are
adaptors with a suitable step up ratio in the transformer, otherwise
the transformer is just 1:1. It's a balun!

>results: just feed from ground to one of the balanced legs. In this
>case, there's an active differential input, and grounding one side will
>do you no good in some cases.

That's because the differential pair input *is* balanced. The only
reason you'd add the optional transformers in this case would be
if you needed to break the DC continuity between the board and a
distant piece of equipment that may not share common power (otherwise
you'd get a nasty ground loop), or because the distant equipment may
need phantom power fed down the cable. Unbalanced inputs have one side
grounded *internally*, balanced inputs don't. The presence or absence
of a transformer doesn't necessarily determine whether you're dealing
with balanced or unbalanced audio.

Pin 1 of the XLR is *shield* ground. You may not want to connect this
at both ends, even in balanced systems, because it can cause a frame
to frame ground loop. Grounding it only at the console end (or better
at the patch field) is usually best.

Pins 2 and 3 are the hot balanced pair, which is which doesn't matter
except for phasing. Traditionally, pin 2 gets the red wire and pin 3
gets the black, but as long as you wire both ends the same, it won't
matter (until somebody else has to come along later and repair one
end, then he'll probably wire it standard and you'll have a phase
reversal).

With the 1/4 inch plugs, the tip is always hot and the ring is
ground (which doubles as the shield connection). Obviously you
can't isolate ground with this type connection, and ground loops,
hum pickup, and RF pickup (at a radio station) will be commmon
and infuriating problems. The solution, of course, is to insert
a 1:1 transformer at the unbalanced end *before* the equipment
connection. This offers DC isolation, breaking the ground loop
and allowing you to single point the shield.

These *baluns* are standard off the shelf items from any professional
audio supplier.

368. ne602 direct conv.

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-15 00:00:00 UTC
From: eeg132@news.salford.ac.uk
Message-ID: <eeg132.36.0@news.salford.ac.uk>
Source record: 108086

Hi, I'm thinking of building a direct conversion Rx using the ne602 dual balanced mod. and a VCO made from shmitt logic (outputs squarewaves).

The resistive load from the ne602's output will feed a high gain opamp (non-inv.) amplifier with a preset rolloff of -20db/dec and a -3db freq. of around 1 khz (i.e. any 741 set for a gain of about 1000), this in turn is followed by a small poweropamp output stage (gain of about 100).

The questions I would like answered are:

Can such a device detect FM as well as SSB and CW?

Would the squarewave VCO cause too many harmonic problems in the mixer?

Is -20db/dec sufficient to filter out any rf left at the output of the mixer?

I intend to vary the frequency from about 1.5Mhz to 20MHz, any ideas on the best frequencies to monitor with such a rig?

Please send any ideas / comments to my e-mail address (post also if you wish).

Thanks,

A.Vilches@eee.salford.ac.uk

370. How to add battery capacity to a vehicle?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-15 00:00:00 UTC
From: butte.wbst129@xerox.com
Message-ID: <NEWTNews.821723304.9289.Pbutterf@butter-pc.ess.mc.xerox.com>
Source record: 108088

I am interested in increasing the battery capacity in my pick up truck to permit it to run equipment for a longer period of time without the engine running. Specifically, I would like to be able to leave my remote controllable dual band rig on as a cross band repeater without coming back to a dead battery. I've considered the following options, but would like comment, feedback and suggestions.

1.
Install a deep-cycle (e.g. marine) battery in place of the existing one. Would select one that fit in the available space and still had the "cold-cranking amps" rating of the existing one.

2.
Install a second conventional battery in parallel with the existing one. Don't know what kind of balancing might have to be done here.

3.
Install a second battery with a manual switch. High Current switch=$$?. Would it have to be at the battery instead of near the dashboard?

4.
Power the rig from a separate lead-acid or gel-cell with trickle charger powered by an ignition-switched circuit. (I already have gel cells with about 20 amp-hours of capacity) Don't know how to construct this circuit to limit current if battery were discharged. (Yeah, I'm ignorant, but learning...)

Thoughts anyone?

Regards,
Paul

The source code wasn't submitted to QST, the software flow chart was,
and they chose not to publish that. There was no accident. QST, being
the fine journal that it is, wouldn't practice the ethics implied.
They bench tested the unit to ensure it did what was claimed. They
aren't going to stake their reputation on something as trivial.

>This is begining to sound like someone danced around the truth a bit in
>the earlier replies.

I fail to understand the statement. Dwayne and Gene did a lot of
pondering on the release of the source before they submitted the
article. They (I can't speak for QST) didn't know peoples feelings on
the source code release. That is why they are releasing the code...
because people want it. All the comments posted and E-Mailed had a
voice and it was listened to. I never know if I did something right
or wrong unless there is feedback. Feedback is a good thing.

There is no dancing, right, or wrong to the situation. What ever
their reasons, they listen to comments. If someone doesn't like the
article, turn the page. Any future articles will have source code
(probley downloadable from the ARRL board).

Thank you and everyone for the great comments!

73,

Glenn

Many readers from this (and related) groups have already visited the radio amateur pages below:

http://www.innotts.co.uk/~asperges/

and left about 250 messages for me since December '95. Thanks. I have replied to all of them individually.

I'm thinking about making a new page for SWLs, who don't seem to be catered for quite so well elsewhere, but I should like some feedback before doing so: should there be FAQs? links? Should there be pointers to schedules etc etc?. Should the style be same or different from the other pages?

If you have some ideas for SWLs, please e-mail me from the pages.

I am still collecting links for the "Friends on the net" for other amateurs with home pages they would like networked.

: but otherwise looks like a zener.

I recently discovered the "It doesn't like much parallel capacitance"
thing, but it's really that it doesn't like a moderate amount of
capacitance: it's stable for large capacitance (4.7uF and above)
and small (4.7nF and below) but potentially not in between. The region of
stability is shown in the TI databook. It's least stable for lowest
voltage (Vka = Vref) and low currents (the capacitances given above), and
unstable at 15 volts only at low current from about .06uF to 1uF.
Note that type of capacitor and lead lengths (parasitic inductance and
resistance) may affect the region of stability.

Not quite, Gary... in the old days it *was* a matched 600 ohm ideal...
today it's "lowest possible source impedance, highest possible load
impedance" for balanced line level. Leads to a lot of confusion when
defining dBm in audio practice, to say the least.

But this ain't ham homebrew, unless we're talking' interfacing old radio
consoles to AM transmitters modified for 160 meters ...

>vy 73, Guenter,

Hi Guenter,

They are tuned by pulling (about 1/2 to 2 inches travel usually, depending on the size) the axis against the suction of the vacuum, or by rotating a screw shaft (5 to twenty turns, usually) that converts the motion to the pull required.

The capacitors are internally like a series of alternating concentric cylinders. One connects to a bellows that allows movement while sealing the vacuum. It telescopes in and out to mesh and un-mesh. There are no friction contacts, and the internal leads are short and wide. So Q is very good.

>when it does there are legal remedies.

I don't want to fuel paranoia among programmers, but it certainly has happened that hardware designs (including items such as PC board layouts) are blatantly offered on a commercial basis without the author's permission. See the earlier postings by N7WS.

Another example involved a hardware design by a VK amateur being ripped off and sold in the USA. By "ripped off" I mean that little or nothing was added to the original design, and the guy who'd done all the work never saw a red cent.

In most of these amateur radio cases, the amount of money involved is only a few hundreds of dollars, or at most a few thousand. So although the legal remedy exists in principle, it isn't possible in practice. Unfortunately some cynical commercial dealers are completely aware of this.

Even more serious is that after such an experience the victim is far less likely to publish anything again - and that is a loss to all of us.

>It's far more important for
>a QST technical article to teach by example than any fear that someone

Sadly, that's no longer true. If a popular homebrew project is ripped off and marketed as a ready-built product, it will sell like hot cakes.

Source record: 108107

If I were to use separate gel cells to power a UHF/VHF rig in my vehicle, how might I shut off the power if the voltage dropped below the minimum level (11.7 volts) documented in the rig's specifications. Is there a simple solid state approach that might be taken? Or will a relay be involved?

Also, to charge a battery from the vehicle's 13.8V system, will a series resistor be sufficient to limit current? Seems the difference in potential ought never to be larger than about 2.5 Volts. Wouldn't a 5 ohm resistor limit current to a safe(?) 0.5 Amps? What does the battery's internal resistance do to the system?

.. and yet another question. My gel cells consist of two batteries of six separate two volt cells each. I have access to additional cells to make two batteries of seven cells each. Nominal potential (two batteries in parallel)of 14V instead of 12V. Is there merit to this? Rig can handle maximum potential of 15.8 volts. Can these cells be charged to that higher potential to increase their capacity? How difficult would it be to voltage convert the nominal 13.8 V available from the vehicle supply up to 15.8V?

I know, lots of questions. And free advice is worth what I pay for it.
;-)

At least here in the US the easiest thing is to hook a volt meter
to measure the voltage. It should be around 48 V when no one is
on line and drop to < 10 V if the phone was in use. That what I
do at the office.

Hello!

a simple question, but can anyone tell me how to use vaacuum capacitors?
These are often mentioned in stateside homebrew descriptions, maybe your
surplus market is larger...

Are they tuned with pressing the axis or rotating it? If rotating, what is
the roation angle and what force has to be applied? Much more than a
standard
capacitor?

Thanks for your answer!

>I fail to understand the statement.

Let me explain it then. Reading this thread, I first received the
impression there was no reason the code was omited other than space and a
lack of understanding people would be interested in it. I received the
impression QST omitted the flow chart basically on it's own.

As I understood your comments, you said the author was concerned about
"giving away two years of work to a manufacturer". That leaves me with the
impression the author's desire was to have the data left out.

If that was even part of the reason for the omission, then everyone should
have just said so instead of implying the omission was due to
forgetfulness or ignorance.

In my opinion, "protecting work" is a very poor reason to omit anything
from an friendly helpful educational article.

Hi Dave !
As I understand you effort, you want to measure the komplex impedance
of your antenna at a give frequency (i.e. 60-j80), insert the data in
your computer and than it tells you how to adjust your tuner.
If i understood correctly (please tell if i did not), that should be
fairly easy. i wrote a procedure that gives you all solutions of
c1,l,c2 for a t-filter configuration to match a certain impedance to
50ohms. that is a long list. now you simply take the solution which
has the highest load capacity (c2=max). This should be the best match
with least loss !
I think the hard part to it is guessing the complex impedance !!!
If you have suggestions, how that could be accomlished, i would be
thankfull to hear.

I think Jim, that you mean ten meters rather than ten feet for antenna
length. Usually in the USA we refer to the antenna as fifty feet in
total length including the top hat. LOWFER's are experimenters in the
160 to 190 KHz range. Lots of good work is being done in that region
under some horrible conditions usually by hams but not necessarily so!

When I bought my truck it had two batteries installed as part of
a "camper" package. One battery is strictly for the engine, the
second battery powers the camper and is disconnected from the
truck battery when the engine is off. When the engine is
running both batteries charge. There is a module that controls
the interconnect between the batteries; I don't know if it is
any more than a simple relay. It may or maynot include some
form of current limiting.

In any case that hookup should be a standard item at an RV shop.
Or, from GM since it came from the factory on my Chev.

Deep cycle (marine) type batteries were not designed for automotive
cranking service. You could do this, but you may not get proper battery
life.

> 2.
> Install a second conventional battery in parallel with the existin
> one. Don't know what kind of balancing might have to be done
> here.

Good choice, but you will probably have to increase the charging
capacity of your alternator. Diesel cars have been doing this for a long
time.

3.
> Install a second battery with a manual switch. High Current
> switch=$$?. Would it have to be at the battery instead of near
> the dashboard?

Unless you used some type of current limiting, you would have to
use a high current remotely controlled switch and heavy cables. The
inrush of current from a fully charged battery to a dead battery could
overheat small wires and burn out low current switches.

4.

Complicated charger circuit would be required to prevent damage to
the gel cells, plus you would not have the capacity for long periods of
operation unless you ganged ten or more together!

> Regards,
> Paul
>
> KB2TCG

Paul, your best option would be to install a deep cycle marine
battery in your vehicle and connect it through an adapter sold for this
purpose to keep a recreational vehicle lighting circuit battery charged.
You can obtain this adapter from just about any recreational vehicle
dealer or service/parts supplier. (Also check J.C. Whitney catalog).
Connect the radio to the deep cycle battery. Connect this battery to
your charging circuit through the adapter. You can drain the radio's
battery completely without becoming stranded because the vehicle battery
will still be fully charged. As soon as the vehicle is cranked, the
adapter starts a regulated charging of the radio's battery.
Since an automotive battery was not designed for this use, and a
marine deep cycle battery was not designed for automotive use, this
option gives you the best of both.

>Is this true?

The normal failure mode is shorted. That's good. If they failed
open, you might have no protection and not know it. A catastropic
failure usually results in the MOV *vaporizing*, so that sort of
failure is definitely an *open*. :-)

Damage can be cumulative, but if the transient is within the joule
limits of the device, it should cause no damage at all.

Yep, and if you aren't careful you'll have an RC relaxation
oscillator too. The best course, IMHO, is to have local
regulation at each module.

That's a lot of octaves! (Or decades even).

>I've been known to use resistive loading in the bias
>lines of low power amplifiers, but this isn't always
>practical.

Well, as you already know, ferrites are probably the best answer. You can get a |Z| real (resistive) part that is useful over a fairly wide frequency range while not presenting a DC resistance. Even if there are resonances somewhere, the Q is lowered and this often helps.

The point I was trying to make was that the shotgun and more-the-merrier approaches often work, but not always. In ham stuff, this is often OK, because we build only one of something and can always fiddle with it. The problems arise when you want to build a bunch of something and normal tolerances bite you.

As designer for the masses, you must be aware of this.

Even in aerospace, we historically have thrown money at things by screening hardware (as the VCO vendor had done with the regulator chip, BTW) to improve yield and reduce variability. Now days, we are being forced to use Commercial-Off-The Shelf (COTS) stuff. This is for two reasons: one, the customer (that's you, Taxpayer) doesn't want the finest anymore and 2, no vendors want to put up with the paperwork necessary to build a handfull of parts, when they can build millions for other people. This scares the hell out of me, but nobody asked me.

The most common method of doing this is a device called a "battery
isolator", consisting of two power diodes on a heat sink. It has three
terminals: Alternator, Battery 1, and Battery 2. The internal wiring is:

```
|---->|---- Battery 1
Alternator -----|
|---->|---- Battery 2
```

When the engine is not running, the two batteries are isolated since one or
both of the diodes will be reverse-biased. Thus the auxilary battery can
be run down without drawing any current from the engine battery. When the
engine is running, power generated by the alternator forward-biases the
diodes and charges both batteries, giving preference to the one with a
lower voltage. Eventually, both batteries will charge to the same voltage.
Usually the vehicle's voltage regulator remains connected to the Battery 1
circuit, so the voltage at that battery is regulated, and the alternator
output voltage is able to rise to overcome the drop in the diode. The
voltage available at Battery 2 is inherently also regulated, since the
voltage drop in the two forward-biased diodes is about the same.

Battery isolators are sold in different amperage ratings, or you can
homebrew one from two suitable diodes and a heat sink. The diodes need to
be rated for the full output of the vehicle's alternator, which can be more
than 100 A in some cases.

How would you attack the problem in a "DC to daylight"
amplifier with no "safe frequencies" to move the
resonances?

I've been known to use resistive loading in the bias
lines of low power amplifiers, but this isn't always
practical.

In my article(s) I've included source code and schematics. I think the problem that some authors have with this is that they think a years work may be grabbed by some (un-nice) character and sold commercial. More than one software author has been paid zilch for his efforts. I've found that a kit that includes hardware cuts this down. And of course my goal is to help translate some of the techno-babble that most component manuals are written in. You know what they say "Examples are worth 1000 words!" Actualy I say "Without a working example you got zilch!" But others may not feel that way. And I think you can voice your opinion by not buying a kit without full source. Or whatever you don't like. On the other hand if there are people who want a nice antenna tuner I don't think it is our place to demand it be removed from QST. Maybe some of those who dislike the no source bits should publish source? Just a mean idea...

Tom, if it were a program like for instance Circad the effect of posting the source would be A: Lose all revenue B: Give away all "trade" secrets. Now I understand that this was not a program but there are those who come from that background who will feel the same. When I published the source to Weekend DigiVFO I did so thinking "This is also hardware" And of course I wanted to help others understand this new technology. If I got 10 Cents from that project it would have been ok with me. Of course many hundreds of people went DigiWacko and I made a few bucks from that piece. A guy who works a year on a project and might be counting on making money on it might not feel the same way. Also with DigiVFO I never felt the software was "done" Others have proven that by sending me new programs based on my code. Neat! Maybe the authors of these UnPublished bits Feel that this is done no room for improvment. I dunno. I do hoever feel that it is up to the author. It is a little like the people who hate contests (or SSTV, Lists, DXers, etc) who say "These guys should all get stuffed" Maybe it is not your (or my) cup of tea but it appears that there are people who like the ATU piece and think enough of it to send off for a kit.

In the USA there is the Lowfer "experimental band" from 160 kHz to 190 kHz, 1 watt, maximum 50 foot antenna (and feedline if used), no license required. There is a fairly large and active group here. Also in the USA, no license is needed for operation below 8 kHz. I don't know of any real radio activity by experimenters down at ELF, but there is some activity with "Earth Radio", which is really just a sheet resistance method of sending signals. Performance can be surprisingly good if you can deal with the power line currents, IE *horrible* hum.

This band is between 160 and 190 kHz. There have been quite a number of articles over the years on various construction projects. The law granting authority to use this band limits power to one watt and antenna size to 10 feet. This size limit makes for some heavily loaded antennas!

Date: 1996-01-16 00:00:00 UTC
From: pfzouave@aol.com
Message-ID: <4dh8lv$cdo@newsbf02.news.aol.com>
Source record: 108047

I was the original poster who created this "Xpert Needed: Zener Diodes" thread. I figured I'd take a moment to thank the dozens of individuals who took the trouble to respond.

The composite answer appears to be this: Yes, the forward biased diodes can be used as a reverse biased zener might, and several individuals have done so in their designs, though there can be troubles related to temperature effects, and the fact that the forward "breakdown" does not exhibit the sharp "knee" that the zener would.

For my particular application (as outlined in the original message), it seems the best route may be to forgo the zener/transistor discrete circuit in lieu of one of the many available 3-terminal supervisor IC's by maxim, panasonic, dallas, and even sony.

Again, thanks to all for their help!!

Source record: 108050

Actually, relay systems to do this are fairly common. My pickup came with the trailer towing package, and it has provision for a second battery in the trailer, charged from the alternator. This is done with a relay. I have added a second battery under the hood for the radios and a winch, which is controlled by another relay. The advantage of this is that by controlling the coil of the relay (rated for 500A) from two places and off, I can parallel the batteries only when charging (normal mode), parallel them all the time (jumpstart myself, or if extra capacity should be needed when winching), or isolate the second for clean radio power or if it goes bad.
If you use a diode battery isolator, you must adjust the voltage regulator or make sure your wiring takes care of the diode voltage drop.
Wrangler Power Products has neat stuff for doing this, including complete kits, battery trays, cables, connectors, fuses and holders, circuit breakers, distribution unit, etc.

In the February "Four Wheeler" magazine one of their articles uses materials from Wrangler to "provide clean power" for a CB rig. They show a 5 watt CB being fed by 4 gauge cable in a sheild. They've got the right idea, and for a loaded amateur mobile rig, 4 gauge isn't too far out. Check out the magazine, check out Wrangler, and tell them I sent you.

Given the response to me from LDG, I think they and the QST staff
misread the audience. The flow chart and binary is available now, for
SASE and formatted PC 3 1/2" floppy, and the source will be available
when it's adequately commented. I've got the flow chart already, and
suspect I could put the code into an 68HC811E2 (2K vs 512 bytes code
space on the A1) with no problem, right now.
I can also see why the QST staff didn't publish the flow chart.

There are going to be more articles for devices using the MC68HC11 from
Dwayne and LDG, with more information available.

The article caused me to do some research on the 'HC11, and I think
it's a cool IC with lots of potential for amateur radio projects.
Check out the HC11 FAQ available at rtfm.mit.edu under
sci.electronics, among other places.

423. Pls Help With Keyer Circuit Question

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-16 00:00:00 UTC
From: jhschutt@figmnt.tayloru.edu
Message-ID: <1996Jan16.174315.2680@figmnt.tayloru.edu>
Source record: 108054

Can you help a neophyte in electronics? I built a keyer that I saw described in the article "An Inexpensive Morse Code Keyer" which was published in 73 Amateur Radio Today in June 1995. Here are the questions.

1. Initially, one of the grounds was bad. This could be due to a mistake made by a rookie. But, maybe not. Has anyone else built this circuit and had any problems?
2. Now that it works, the volume is barely audible. Any idea what I shoul try to correct this? Here are some options:
a. Would a bad 2N2222A cause this? That's the amplifier transistor.
b. The parts list says to use a Radio Shack 273-091 Piezo Speaker.
The author says that this is a 1200 ohm speaker, but the RS 273-091B is a 3500 ohm speaker. WOuld this cause the very low volume?
c. Am I correct in mounting the electrolytic cap with the - side towards ground? I thought so, but someone told me that the "curves" side of teh symbol was the positive side. Every reference that I have shows it to be the negative side-- the side closer to the (-) of the battery (ie., ground.

I'd really like to hear the keyer. I really appreciate your help. Because our News server crashes regularly, e-mail replies are preferred. THANKS. I know that it takes time and effort to reply to a post.

If remember correctly, I would float pin 10 of the MB8719 and then place a 1K pot on this pin to ground. By adjusting the pot, the pll would go thru 3 states. One is the normal state, one is a +640KHz and the other somewhere in between is +1280KHz which brings you to 28.685 on CH40. You need to readjust the VCO coil which is the one that contains wax and has red plastic until the vco oscillates at this new frequency range. Once this is done you need to retune the TX and TX coils to peak the RX and TX on the new range.

73's
Hope this helps.

> . . .

This doesn't answer your questions, but. . .

A big potential problem with direct conversion receivers is AM demodulation. This is caused by
even-order distortion in the mixer. The symptoms are a constant background din of audio caused by
demodulation and amplification of loud AM (BCB or SW) signals. I don't have direct experience
with the NE602 but have been told by reliable sources that it's much more susceptible to this
than a diode ring mixer. If you do use an NE602, I recommend preceding it with a filter which is
narrowband enough to greatly attenuate potential sources of AM. This requires quite a narrow
filter if you want to use it on 40 meters.

>>
>
>73 from Ian G3SEK

Ian,

I think we miss the point. When an article is published as a teaching aid, it is given away to everyone. The author should be prepared for that.

For example, I designed some phased receiving loops for HF many years ago. Because I decided I wanted to market the design, I chose NOT to give any of the information to anyone.

But if I published the idea and gave it away, it's gone. If someone copies it and makes money, I may not like it but....tough luck. I made my choice when I decided to give it away. I'll be damned if I would print part of it and make the readers come begging just to "protect my work". That decision is history when I decide to help others duplicate my work.

I know you make choices like that Ian. You sent me a regulator board layout for HV supplies, and I make my living selling high power amplifier designs. I may make money from something that I "stole" from you. If you didn't want to run that risk, you wouldn't have sent me the board. I'm sure you knew I make money from projects like that, sometimes substantial money. And sometimes I give work away just to help people because I like to help. Especially when they help other people.

I think articles are published to help people understand how something works. If you don't want your idea used by others, don't publicize it. Once you decide to share it, you've shared it. If someone wants to make money from it, more power to them.

I wonder where we'd be if Ohm kept his work secret so people wouldn't steal it? Maybe it'd be Ian's law, eh?? ;-) How many of us have sent Ohm's desendents a Royality payment? How many of us watch someone else do something, and copy the idea? How about Edison?

Come on now, if you don't want your idea "stolen" keep it to yourself. Don't print it under the guise of helping teach and then cry thief.

73 Tom

> it's well known that a grapefruit will supply more juice...

The voltage difference between copper and "silver" should be the same with the two fruits, so the humorous comment above is probably correct, the grapefruite should have more amp-hours in it. As long as the lemon circuit isn't relying on the low capacity of the lemon for voltage regulation...

One concern is modern vs. original coinage -- our current quarters have more copper volume (though not area?) than our current pennies. With modern sandwich quarters they'll be a wasteful "eddy" current between the sides and edges of the quarter. Sandwich pennies have sealed edges, so no such problem. Whether this effect will be measurable I don't know.

Don't eat the fruit afterwards, it'll have been Plated.

Good luck,

Date: 1996-01-17 00:00:00 UTC
From: Paul Christensen <paulc@jax.se.continental.com>
Message-ID: <4djtee$7bi@usenet.continental.com>
Source record: 107977

>For line level (used to be +8 dbm but the industry is switching to +4 dbm)
>the impedance is 600 ohms.

And even more recently, dBu is being used. In the past ten years, voltage (not power) transfer has been the preferred method of interfacing audio circuits. The popularity of dBu stems from the fact that newer audio devices have output impedances well below 600 ohms. In high-end, professional broadcast applications, the trend seems to have moved toward 50 - 55 ohms. All other things being equal, there's less high frequency roll-off over extended distances of audio cable when using a lower source impedance than 600 ohms. Therefore, dBu only references *voltage* at 0.775 volts, irrespective of impedance.

With the advent of bipolar, +/- 15 volt power supply rails to supply the low-distortion active devices, the manufacturers quickly found that ~ +20 dBu was the maximum output level of the circuit. At +8 dBu, or +8 dBm into 600 ohms, this meant that only 12 - 15 dB of peak-to-average headroom was afforded. Allowing for human/operator sloppiness, the real headroom figure is actually less. Even today with digitally produced sources, 20 dB of headroom is sometimes not enough (Anyone hear Telarc's digital recording of the 1812 Overture on a real mean sound system?)

End of sermon.

>defining dBm in audio practice, to say the least.

And that bridging technique leads to lots of RF pickup too, which is
why our plants are staying +4 dbm houses with real terminations on
our lines. It means we still have to use DAs instead of simple build
outs, but we're willing to pay that price.

Gary

444. PLL FM Demodulators??

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-17 00:00:00 UTC
From: Jay Wicklund <jwicklun@mail.halcyon.com>
Message-ID: <NEWTNews.821903720.21949.jwicklun@mycroftxxx.halcyon.com>
Source record: 107980

Hi all, I'm a little curious. I've been away from RF design for more than a few years, and am just getting back to it. About 20 years ago, using a pll for fm demodulation seemed to be the "wave of the future". Signetics and others were designing chip after chip of pll demodulators. What happened?? Some of those old chips are still around, but all of the more complex IF strip/fm demodulators seem to use other techniques such as quadrature demodulation with a phase shifter. Is it simply a case of simplicity or is there some sort of problem with the pll system?

Thanks.....73 de KI7RH (Jay)

>Would select one that fit in the available space and still had the
>"cold-cranking amps" rating of the existing one.

That's probably a bad idea from two directions. Since you still only
have one battery, you can still discharge it enough with the radio
equipment that the truck won't start. And second, deep cycle marine
batteries are constructed differently than starting batteries, good
luck on finding one with the same "cold cranking amps" in the same
form factor as the starting battery.

>2.
>Install a second conventional battery in parallel with the existing one.
>Don't know what kind of balancing might have to be done here.
>
>3.
>Install a second battery with a manual switch. High Current switch=$$?.
>Would it have to be at the battery instead of near the dashboard?

Diode steering. That gives you an automatic "switch", and is the way
RV kits work. The circuit looks like this

D1 D2
Bat 1+ -x----|<-----x----->|---x-- Bat 2 +
| | |
| Alternator + |
To starter, ign, To Radios
etc

The alternator approximates a constant voltage source when running.
It will charge both batteries (with the one with the lower state of
charge initially hogging most of the current, but that's Ok, they'll
equalize eventually). Since the ampacity of the alternator is sized
to quickly charge only one battery, you'll have to drive a while
longer to charge both batteries, but it'll still get the job done

unless you only drive very short trips.

The diode voltage drop can be troublesome on some vehicles, GM and
Ford/Chrysler require slightly different wiring to deal with that
so that the alternator excitation is regulated up to compensate.
The RV kits come with hookup instructions which will handle that.
Read the package.

>4.
>Power the rig from a separate lead-acid or gel-cell with trickle charger
>powered by an ignition-switched circuit. (I already have gel cells with about
>20 amp-hours of capacity) Don't know how to construct this circuit to limit
>current if battery were discharged. (Yeah, I'm ignorant, but learning...)

A power resistor will serve as a trickle charge current limiter. Use
the right half of the circuit shown above, but add a resistor in series
with D2 to limit charging current to Bat 2 to something equal to about
.1C of the gel cells. The gell cells will be flat at 10.5 volts, so the
resistor needs to limit current to 2 amps for a 3.3 volt drop, or
about 1.65 ohms. This will produce a "taper" charge, but that's Ok
too, it just takes longer for the battery to fully recharge. If the
gell cells (or a regular battery) go completely flat, IE 0 volts,
they'll *self-limit* until their terminal voltage gets up around 10
volts, so you needn't worry about that, IE it's devilish hard to make
a completely flat lead acid battery *take* current.

>suffocates anything past a few Hz and accept the result
>as reflecting the RF energy at the frequency of
>interest? (is it 'cos the output of the mixer is
>AC-coupled internal to the mixer? :( )

The problem is noise: you will get downconverted AM noise from the LO, and you will have to deal with 1/f noise in the amplifiers following the mixer. you will also need a mixer that has an IF response to DC. but lots of mixers do this.

Finally, there are spurious responses and images that will cause trouble at low IF frequencies.

Hi Leon and All,

I am repairing my Heathkit Printer. It broke in 1993 and being unemployed, currently is taking me longer than expected to finish the repair. I need a 6.7584 MHz crystal in a HC-33 case for the main logic board of the printer, but can't find anyone that makes just one. Does anyone know of anyone that makes this crystal or has it in stock?

The Heathkit part no. for the crystal is 404-623 and is identified in the circuit as Y201. I do not have any other specifications for the crystal. Can anyone offer any help?

From: pfzouave@aol.com
Message-ID: <4djhu6$cij@newsbf02.news.aol.com>
Source record: 107984

Recently I built a room in a friend's house for the purposes of recording music. The room needed power, so I went to the breaker box in search of a circuit that I could get power from.

I found a 20 amp breaker feeding a string of three outlets: Thats it, thats all that was on that circuit. I fished my wired down the wall and added my recording room outlet to the end of the existing string. So far so good.

What concerns me is this. The wire from the breaker box to the first outlet appears to be #12. So is the wire from outlet 1 to 2. From 2 to 3, the wire appears to be thinner romax (#14?). All the wiring I added (from the 3rd outlet to my room) is all #12.

For starters, 20amps seems to be an awfully large breaker for three lousy outlets. Secondly, While #12 wire in the string could probably carry an overload until the breaker tripped, Im concerned about the #14 link. So, the question is this: Should I replace the 20 amp breaker in the panel with a 15 amp unit?

Please email your response if possible, and thanks.

: running the truck battery down with external devices. Also he rigged
: up a solonoid to be able to start the truck from both batteries if the
: truck battery is low from leaving the lights on etc.

I placed a second, deep-cycle, battery in the bed of my pickup and use a dual battery isolator (available at most any auto part store) to connect both the new battery and the original battery to the truck's alternator. My ham gear is connected to the deep-cycle battery. I got tired of not being able to start the truck after leaving the radio on in repeat mode. All of the wiring was done using No. 6 welding wire.

The dual battery isolator is basically a set of high current diodes which allows the alternator to charge both batteries at the same time while keeping the batteries isolated from one another so that a weak battery will not draw down a good battery or allows you to draw from one battery without drawing on the other. In my Ford Ranger, the alternator voltage sense is done at the primary fuse panel; therfore, the voltage drop of the diode is automatically compensated for.

Fair Radio in Lima, Ohio, has surplus panel mount reed frequency meters. You can also use an
Automotive type tachometer, which essentially is a clipper/differentiator/rectifier/VM type of
frequency meter. 60 Hz is 1800 RPM on a 4 cylinder engine scale.
If you care to build your own, approximate circuit constants for 60Hz center scale on a 200ua
meter movement would require a 47K ohm series limiting resistor, an 8v zener diode clipper, a .3uf differentiating capacitor, a small bridge meter rectifier, and a 10K ohm calibrating rheostat to shunt the 200ua meter movement.
You can also use an ordinary synchronous motor clock by timing the second hand against your watch.

>That's because the differential pair input *is* balanced.

Not always. OK, I may be nit-picking Garry, but in professional audio applications, there's a big difference. The terms "differential" and "balanced" are not synonymous in audio applications. It's possible to have a differential op-amp single-stage input for instance, but this should not be construed with a true, balanced input. Here's why: typically, the input impedance of a of the non-inverting (+) differential input is *at least* twice the impedance of the inverting (-) input, with respect to ground. The actual amount is a function of the stage's gain. Generally, under these conditions its necessary to tie the inverting input (through the matched input resistors) to ground. On the other hand, an active, differential *instrumentation* input offers a truly a balanced input with respect to ground. Oftentimes, a three-stage op-amp is employed as the differential instrumentation input.

The fundamental difference between the common, single-stage differential input, and the instrumentation input lies in the common-mode rejection characteristics of the circuit. True, most other parameters will measure the same (ex. frequency response, harmonic and intermod distortion characteristics), but in R.F. or long cabling environments, the instrumentation input is far superior.

>Pin 1 of the XLR is *shield* ground. You may not want to connect this
>at both ends, even in balanced systems, because it can cause a frame
>to frame ground loop. Grounding it only at the console end (or better
>at the patch field) is usually best.

I've found this to be true too. Centerpoint audio grounding seems to have fewer problems in hostile environments.

>Pins 2 and 3 are the hot balanced pair, which is which doesn't matter
>except for phasing. Traditionally, pin 2 gets the red wire and pin 3
>gets the black, but as long as you wire both ends the same, it won't
>matter (until somebody else has to come along later and repair one
>end, then he'll probably wire it standard and you'll have a phase
>reversal).

Ahhh...the never ending story of how pin 3 became high in the first place! I suspect that in the U.S. it had become a "standard" among audio engineers before it became an ISO or AES international standard.

>With the 1/4-inch plugs, the tip is always hot and the ring is
>ground (which doubles as the shield connection).

Unless it's a "differential" or "balanced" device. Then, the three circuit 1/4" plug is "tip-ring-sleeve," with the sleeve grounded or

left floating, depending on the system ground convention.

Hi,
I don't know the 4CX250K but a lot of other coaxial tetrodes.
I think the pinout of this tube will be similar to the "usual" coaxial
pinout:
(Seen from the "lower" end)
Heater, Heater/Cathode, Control Grid, Screen Grid, Anode.
The electrical parameters will be the same as 4cx250b, maybe
the frequency-range is bigger because of the coaxial pinout.

Difficult to find a deep cycle battery that would have the cold
cranking capacity of an automotive battery. They are basically two
different animals. The deep cycle is meant for a steady load over a period
of time and the automotive is designed to be loaded severly for a short time
and recharged rapidly.

>
>2.
>Install a second conventional battery in parallel with the existing one.

With this one it would take longer to kill the battery of the
vehicle but it would still happen. Probably some night around 2 or 3 am and
in the wrong part of town. OOOOO Bad. :-(

>learning...)

This very last part is REALLY good. And a combination of 3 and 4 is
probably the best thing to do.

Here is what some of the people around here do.

Go to a travel trailer dealer and ask for an "Auxilary Battery Isolator". This unit is a 3 terminal unit that isolates two batteries from each other on a vehicle so that one will not drain the other as it is used. This is basically a good sized heat sink with two diodes on it.

The two diodes have their anodes tied together. The terminals may be labeled something like Alternator, Battery 1 and Battery 2.

Disconnect the heavy wire at the alternator and connect it to the terminal marked Battery 1 or it's equivalent. Next run a wire of equal gauge or heavier from the alternator where you just removed the wire to the isolators Alternator terminal. At this point the vehicle is still wired like it was before but there is a diode between the alternator and the battery. This will not affect the vehicle.

Now here is the part that will help you out with the radios.

Mount a battery someplace on the vehicle in a battery tray or a battery box that can be tied down SECURELY. You do not want the battery just bouncing around in the vehicle and bumping into things or spilling.

The negative post of this battery, which could be a deep cycle battery, goes to the frame or chassis of the vehicle. Someplace that is at the same potential as the negative post on the first battery. Connect a wire to the Battery 2 terminal on the battery isolator. This should be a fairly heavy wire as it will be the one carrying the charging current to the second battery. Connect the other end of this wire to the second battery positive terminal.

What this does for you is it gives you two batteries on one vehicle that are electrically isolated from one another. Tap into battery 2 for the power to your radios and any other acessories that you want to run on your vehicle.

The operation is totally automatic and one other benefit of this is that if Battery 1 should die for some reason. Now you can give yourself a jumpstart by connecting positive of battery one to positive of battery two with a jumper cable and starting your vehicle.

It really shocks someone the first time they see someone jumpstarting their own vehicle from their own vehicle. :-)

>
>Thoughts anyone?

Well I guess that is what I would think about Paul. :-)
Good luck and I hope this helps you out.

Good suggestion. Let me add that the capacitance requirement is actually
EITHER less than 1000 pF. OR MORE than 4.7 uF., according to the
data sheet. I found that the 4.7 uF. MUST be a tantalum not a ceramic,
or it will oscillate. It depends on the ESR of the tantalum for stability.

QST just did a feature on this very subject. I'll just give a quick condensed generic version. You need remote software for your PCs. You can use PCAnywhere or Remote2 or something similar. These programs let one computer control another just as if you were at the keyboard and screen of the controlled computer. Now all you need is rig and antenna control software. There are a number of packages to choose from. You run that on the controlled PC, just as if you were sitting at its console, and control the rig with the package. You'll need a second phone line and a phone patch to get audio in and out of the rig to you at home. That's it.

I agree with Tom that a person makes a choice either to publish his/her findings and share the information with all others, or to keep part or all secret in order to maximize the profit from it. I've done both, with QST articles and with proprietary software. I don't think anyone can reasonably fault a person for making either choice.

What's causing a problem is the publication of the article (and a similar keyer article a while back) which looks, walks, and quacks like a construction article but isn't. A critical component is available only from the author and can't be duplicated at home. In my mind, this makes disqualifies the article as a construction article and makes it an advertisement.

When most of us decide to go the for-profit route, we have the expense of selling our goods. Advertising is one way, with QST ads costing about $4000 for a black-and-white page. The question for us ARRL members is whether we think this is an appropriate way to use editorial space in QST or to give away valuable advertising. Indeed, it does this regularly as "new product announcements". But should the article have been presented as a new product announcement rather than regular editorial content? And was it selected for inclusion using the same criteria as new product announcements? Do we ARRL members want our magazine (yes, our magazine) to use its editorial space this way? Let your director know what you think.

I wish you'd asked before buying the Motorola (Batwing)
speaker-mike. The stock Radio Shack plug-in version is on the
order of 20 bucks which is probably less than you'll spend on
the motorola version not counting labor and time of course.
The Motorola speaker is probably 40 ohms or so which means it
will have low and unsatisfactory audio output.
Wire the speaker leads directly to a 1/8 inch phone plug.
The PTT and Transmit Audio for the HTX-202 are both on one line
to the mike jack, the smaller jack. Try wiring the PTT switch
in series with the motorola mic element going toward the
miniature plug. If this doesn't make the rig transmit when the
PTt switch is pushed, try putting a 10K to 20K resistor in
parallel with the microphone element.

```
Mic element
... PTT switch
| |-----x--------/--------------------o tip of min. plug
| |-----x-----------------------X Shield/gnd of min. plug
...
x = points to attach 10-20K resistor if needed
```

```

462. Radio REPAIR resource?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-17 00:00:00 UTC
From: Jim Devenport <jdevenport@lanl.gov>
Message-ID: <4dj857$dbv@newshost.lanl.gov>
Source record: 108063

Is there such a thing as a radio *repair* newsgroup ?
I am particularly interested in a schematic/service info for
a Uniden CR-2026 SW receiver at the moment.

I didn't see the original post, so I'll tag along here.

If your pickup truck happens to be a GM model that had a diesel option, you might find that you can buy a second battery tray from the dealer. (The diesels used two batteries in parallel) My 1986 4X4 Suburban did. The mounting holes were already in place too.

Source record: 108065

Generally, yellow is used to mark the 455khz IF Xformers, black is the IF output and red is the local oscillator. I used to work in a consumer electronics repair shop and this is how most japanese comsumer type receivers are. Every manufacturer can do as they please, so, take this advice with that grain of salt. One can also deduce the function of a transformer or coil by looking at it's position in the radio's circuit. If it looks like an intermediate stage, as in there are some circuits before and after it, then you most likely have an IF transformer. In most cheap radios there is bound to be an IF transformer somewhere, if the one you find at first doesn't work, try some others.

Then again, for long-winded QSO's I'd use a grapefruit. After all, it's well known that a grapefruit will supply more juice...

It doesn't, nor does it need to, a megavolt transient is quite sufficient
in itself.

I would use 2 separate batteries. My father set up a simular system in his truck to use with an inverter and power tools. You can purchase a charging device from any RV shop to charge the RV batteries from the truck charging system. This has the advantage of never chancing running the truck battery down with external devices. Also he rigged up a solonoid to be able to start the truck from both batteries if the truck battery is low from leaving the lights on etc.

I don't have any experience with GEL cells, but if you have room under the hood for a small automotive battery I would use that.

Good Luck

I remember as a school project my Grandfather and I built a XMTR that was powered by a penny and a quarter inserted into a grapefruit. Well, my son needs such a project for school and my Grandfather is no longer with us. Can some kind person point me in a direction where I might find plans for this XMTR?

Probably not the one your grandfather built, but. . .

Try "Lemonized QSO" by Bob Culter, N7FKI and Wes Hayward, W7ZOI in QST, March 1992, p. 18. I dunno if I'd power it with a grapefruit, though, it might put the squeeze on the transistor.

470. Announce: New RF Design sw for Windows

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-17 00:00:00 UTC
From: Jon Jenkins <academic@onthenet.com.au>
Message-ID: <4djn7l$rqt@diablo.OntheNet.com.au>
Source record: 108071

RF: The Analog Analysis Program

by Academic Technologies

RF is a new inexpensive circuit simulation sw package for
Windows, Windows 95 and Windows NT. It is primarily
intended for Radio Frequency design but is applicable
to all frequencies.

Come and have a look, visit out Web site at:

http://www.onthenet.com.au/~academic/Welcome.htm

or download the readme.txt and rfdemo.zip demo
version from:

ftp.onthenet.com.au in /pub/acdemic/

or mail us at:

academic@onthenet.com.au

Briefly RF has the following functions:

Tools
Convert between S,Y,Z and ABCD two port parameters
Design Butterworth and Chebichev Filters
Design and analyse coil and wire inductors
Sophisticated Microstrip design and analysis
Design parallel, series resonators and LC filters
Complex/Polar calculator

Compnents
Capacitors (includes parasitics)
Resistors (includes parasitics)
Inductors (Q included)
Curve fitted S parameter devices and whole circuits (fit types:
rational, polynomial, spline, ls, linear)
OpAmps
Transmission Lines (ideal and lossy, open and shorted)
Transformers (ideal and non ideal, leakage inductances and resistances)
FETS (all parasitics)
Tapped Inductors (Q and parasitics)
Beta controlled current sources (all parasitics)
VCCS
Mutual inductors (all parasitics)
Source and Loads
DC source

Analysis Facilities
Swept frequency (Full and Nodal)
Single frequency component tolerance
Swept frequency component tolerance
DC bias point analysis
Pulse analysis (Fourier simulated)

Text Output
Transducer gain
Linvil c stability
Stern k stability
Input impedance
Output impedance
Input admittance
Output admittance
Voltage gain
S11, S12, S21, S22 S parameters
Input reflection coefficient
Output reflection coefficient
Maximum transducer gain possible
Source admittance/impedance to obtain Gtmax
Load admittance/impedance to obtain Gtmax

Graphical Output
Voltage Gain
Transducer gain
Input impedance
Output impedance
S11, S12, S21, S22 S parameters
Input reflection coefficient
Output reflection coefficient
Pulse time trace
Multiple "tagged" plots
Autoscaling or manual scale
Auto cursor tracking (warps to and displays the nearest
points) or absolute
Points or line traces

Getting crystals made isn't at all expensive. I can get custom crystals
in about a week here in the UK for less than #10.

I hope everyone remembers to use fuse links at each end of the accesory battery line. Nothing worse than getting in a wreck (or even just having the insulation get cut) and being in a burning vehicle!

And secure the battery well. The damn things hurt when the hit someone in the head. Gary had a good point about starting current of deep cycle batterys.

73 Tom

476. WANTED: HC25/U or HC50/U Crystals

Newsgroup: rec.radio.amateur.homebrew

Go down to your local auto parts store and buy a 5/16 stud of a proper length.
I think might fit the bill.

Good luck....Gary KF9CM

478. QST UHF Noise generator

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-18 00:00:00 UTC
From: Allen Wallace <allen@dtint.dtint.com>
Message-ID: <4dlv6o$bni@itchy.itsnet.com>
Source record: 107996

I!m trying to build a noise source, based on the QST article of about 2 years ago.

I!m too cheap to buy a NoiseCom diode, and I!d like to try a 1N21 microwave diode instead. I also understand that the Base-Emitter of microwave bipolar transistors can generate significant Excess Noise.

Does anyone have any experience with generating noise with these devices? How might they compare to the NoiseCom diode with respect to ENR and frequency?

The final use for the noise source is to amplify the noise with 6 or so MMIC amplifiers and use the noise with my spectrum analyzer to measure filter response, etc, up to 2 GHZ. The noise hopefully should be flat across the spectrum.

73,

Allen Wallace N7CGH

479. Needed: uA757 IC

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-18 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <821989353.6913@pinetree.microserve.com>
Source record: 107997

After troubleshooting my rig for a tricky receiver problem, I've determined that the IF amplifier IC has failed. The chip is a Fairchild uA757 DP.

Unfortunately, there doesn't seem to be a substitute for this in the general replacement semiconductor lines. If anyone has one or two of these that they don't need, I'll buy them. Alternately, can anyone recommend a Fairchild distributor for this part, or perhaps a cross reference to another device?

73,
Jack WB3U

>>a smaller one is attached from the base to ground.
[snips in consideration of bandwidth]

And if the collector has the slightest bit of inductance to an AC short to ground (i.e. like a few inches of wire or board trace) you are gonna have the goldurndest grounded base oscillator you ever HAVE seen.

Old trick is to put just a few ohms (like 20-50) of real resistor between the capacitors and the base. Cuts down the chance of oscillation to that of winning an argument with the spouse -- slim and none.

_____________________________________________

1.0 What is BASIC Stamp ?
1.1 What is L.O.S.A all about ?
1.2 How can I contribute to this list ?
1.3 Where could I find L.O.S.A ?
1.4 List of contributions.
1.5 Credits and other things.

_____________________________________________

1.0 What is BASIC Stamp ?
-------------------------

This is being written for people who have no idea of what a BASIC
Stamp is...

BASIC Stamps are small reprogrammable single board computers (SBC)
that run BASIC programs and are made by Parallax, Inc. in US. At
first glance, they may seem fairly minimal - and in fact, they are.
But with software that fully utilizes all available hardware, the
Stamps give you powerful features - without the cost of hardware.

Their low cost and simplicity make the Stamps perfect for many
prototyping and control applications. It's suitable for electronics
hobbyists as well as electronics professionals in many different
areas.

Typical application areas for BASIC Stamp's are...

- General electronics
- Home automation
- Robotics
- Mini PLC
- Education
- Prototyping
- HAM related applications
- Special effects in films
```

- Industri control
- Geological instruments
- Computer peripherals
- Scale model hobbyists

As an talent engineer and technical writer expressed it...

- BASIC Stamp is the 555 of the 90's !

1.1 What is L.O.S.A all about ?

I started to compile L.O.S.A because I know there are lots of great ideas and many problems that are solved with the BASIC Stamp and the main purpose of this list is to get an idea of what other people are using their BASIC Stamps for and maybe get some inspiration or hints.

Remeber it's up to all of us if this list are going to be any good and I'm looking forward to receive a description of your application.

1.2 How can I contribute to this list ?

If you have done something with the BASIC Stamp (big or small) that you are willing to tell others please use the form given below and write a short description, nothing fancy is needed just a simple explanation. If you have source code to share that's even better but it's not necessary.

Then e-mail the form to:

cj@algonet.se

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill in the L.O.S.A form on the Web-page...

http://www.algonet.se/~cj/losa.html

Title : Robo-Cat [# 001]
======================================================================
Date : 950807
Author: Gustavson Guy W.
E-mail: GWGUSTAVSO@mpg.norstan.com
----------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: N/A
Filename : N/A
URL : http://www.winternet.com/~bigfoot/cat.html
----------------------------------------------------------------------
Description :

My cat, Kesha, was recently diagnosed with Heptic Lipodosis. Or
"Fatty Liver", basicly what this means is that for some reason he
stoped eating and his liver started converting body to useable
sugars. The fat deposists biuld up in the liver and cause severe
liver damage. Because the liver isn't working well the cat feels
crappy and wants to eat even less. The treatment for this disease is
to run a tube down down the cats nose into his stomach, or a PEG
tube through the abomine wall into the stomach and feed the cat a
liquid diet this way.

I love my cat, but I can't be there every three hours to feed him
through the tube for a month. Something about work and deadlines and
such. So I went to a local supplus house and got a tiny motor driven
pump, a case, some switches, a micro switch, ect...

The micro switch is mounted such that the switch trips for every
rotation of the pump shaft. The stamp turns on the pump for on a
single rotation at intervels programable from the controll switches
on top. An alarm buzzer and LED flash if the pump fails to run for
any reason. The unit is programable for 9 differents deleviery rates.

Now he gets a slow continuious feeding and he seems to tolerate this
better than the 100ml feeding every three hours.

Title : Logic Rudder [# 002]
======================================================================
Date : 950812
Author: Christer Johansson
E-mail: cj@algonet.se
----------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : LRUDDER.ZIP
URL : http://www.algonet.se/~cj/filelibrary/BS1-IC/
----------------------------------------------------------------------
Description :
```

Many of the new and very realistic flight sims available today needs rudder to let you get full control. This one uses a digital pot from Xicor (X9104) and 10 other components. Connects to a standard IBM-PC game port and power is taken from the port.

It uses two micro switches for controlling the rudders left or right and to indicate when rudders move there is a red LED that lights up when you press the micro switches and to indicate center there is a green LED. If you press the both micro swithes the rudder will automaticly return to center position.

There is a trim pot to set the desired step rate from slow to very fast and the Xicor pot has 99 steps wich gives a fair resolution.

```

Title : Tone Decoder [# 005]
=============================================================================
Date : 950926
Author: Bob Blick
E-mail: Bob_Blick@redwoodfn.org
-----------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: Soon
Filename : N/A
URL : http://www.execpc.com/~bblick/stamp.html
-----------------------------------------------------------------------------
Description :

Listens for telephone touchtones, displays phone numbers on LCD
screen and echos them out RS-232 port. Circuitry fits in prototyping
area of rev D Basic Stamp:

Microphone preamplifier, touchtone decoder IC.

=============================================================================
Title : Pager [# 006]
=============================================================================
Date : 950928
Author: Don McKenzie
E-mail: donmck@tbsa.com.au
-----------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : PAGER.BAS
URL : ftp://ftp.parallaxinc.com
-----------------------------------------------------------------------------
Description :

This program for the Basic Stamp is used to monitor 4 hardware
signals. If a change takes place, (after testing for a false trigg-
er) then a cheap 2400 baud MODEM is used to dial into a Telecom
Alpha-Numeric pager. It leaves a message which consists of a 2 digit
I.D. (01 to 99) followed by the 4 signal levels of pins 3 to 0.

Status of the signal levels message: 0=Low, 1=High. EG: "011110"
means Unit "01" has pins 3, 2, and 1 high, and pin 0 is low.

A "Ring-In" feature is also included. By ringing the MODEM for a
short period, then hanging up, the Stamp will dial your Pager and
report the current hardware status of these four signals.

This program uses about half of the available memory, so if the user
wishes to add enchancements such as "Multiple Ring-In's" say within
a minute, for a command selection, there is plenty of program space
left.

Title : HexWalker Mobile Robot [# 007]
```

```
========================================================================
Date : 950929
Author: T. R. Thornton
E-mail: mandtsys@ix.netcom.com
------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D or BS1-IC
Code available: YES
Filename : WALK.BAS
URL : N/A
------------------------------------------------------------------------
Description :

HexWalker is a six legged mobile robot that is controlled by a BASIC
Stamp or BS1-IC, and driven by three servo motors (similar to Futaba
S148). It is the simplest walking machine architecture that can walk
forward, backward, and turn left or right.

========================================================================
Title : Robo Bug [# 008]
========================================================================
Date : 951003
Author: David Novick
E-mail: dkn@cimar.me.ufl.edu
------------------------------------------------------------------------
Stamp model : BS1-IC
Code available: YES
Filename : N/A
URL : http://www.me.ufl.edu/~dkn
------------------------------------------------------------------------
Description :

Using two stamps, a robot with six legs (2 degrees of freedom each)
was able to walk and turn (at this stage, not very gracefully).

========================================================================
Title : EXPBOT Robot controlled by Stamp [# 009]
========================================================================
Date : 951009
Author: Marvin Green
E-mail: marvin@agora.rdrop.com
------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : EXPBOT.BAS
URL : E-mail author and he will send it
------------------------------------------------------------------------
Description :

This program allows a cool robot to move abound a room in search of
light. Like a moth. Simple program changes can dramatically change
the robots behavior.
```

```
=========================================================================
Title : Andrews Ever Evolving Lego Robot [# 010]
=========================================================================
Date : 951119
Author: Andrew H. Hochheimer
E-mail: softarts@ciaccess.com
-------------------------------------------------------------------------
Stamp model : BS2-IC
Code available: YES
Filename : N/A
URL : http://www.wincom.net/~softarts
-------------------------------------------------------------------------
Description :

Currently the robot can only navigate to the brightest light source
in a room. It's current operation mode has four major steps: - Scan
a 180 Degree Field of "Vision" taking light level readings, and
determining the brightest direction of light. - Decide if it needs
to turn left, right, or continue moving forward. - Check for colli-
sion with an object while moving, if a collision occurs, display the
total travel distance on the display - Move forward for 1.5 Seconds
and then repeat the process.

Currently I am using Two Futaba FP-S128 Servos (any RC Car Servos
would work) one to sweep it's "sensors" form left to right, and one
to "stear" the robot.

You can see pictures and more information on my homepage, just
follow the lego robot link.

=========================================================================
Title : Factory Monitoring System [# 011]
=========================================================================
Date : 951120
Author: Paul Willemse
E-mail: pjwill@merlion.singnet.com.sg
-------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : N/A
URL : E-mail author
-------------------------------------------------------------------------
Description :

The system presently consists of 4 Basic Stamp units. Each monitors
up to 5 inputs. The inputs are 'digital' (switches) and/or analog
(temp, airflow, current, etc using commercial sensors). All stamps
communicate the results via serial mode to a Macintosh (Yes a Mac!)
where the results are graphically displayed and monitored. Alarms
are set for certain conditions.

The transmission is simple, one way only. Each stamp sends the info
at a 'random' interval not exceeding 2 seconds. The message format
```

is fixed, the Mac will throw away any conflicts in case two or more stamps transmit at the same time. BTW this happens very seldom. The max time any stamp can be 'absent' from the chain before an alarm is raised is six seconds (failure, transmission collisons, etc). This is controlled by the Mac.

The 'system' is presently in beta test, the client wishes to expand up to 20 stamps. At that point we will likely use the BS1-IC or BS2-IC on custom boards located around the facility.

Code is available upon request (e-mail) partial, some is proprietory to my client.

```
==========================================================================
Title : Wave to the Cats/Desk Temperature [# 012]
==========================================================================
Date : 951121
Author: Paul Haas
E-mail: paulh@hamjudo.com
--------------------------------------------------------------------------
Stamp model : BS1-IC
Code available: Yes
Filename : See web server
URL : http://hogwild.hamjudo.com/cgi-bin/stamp
--------------------------------------------------------------------------
Description :
```

The Stamp has a serial connection to web server, a cardboard hand, a servo motor to move the hand, and a DS1620 thermostat chip to measure the temperature. The web server can request the current temperature or start the hand waving. See the web page for the source code for the temp and the web server.

It's mostly useless. The cats ignore the hand. A few people find it entertaining.

```
==========================================================================
Title : Gamer's Die Roller [# 013]
==========================================================================
Date : 951122
Author: Larry Tremblay
E-mail: ltremblay@domus.com
--------------------------------------------------------------------------
Stamp model : BS2-IC
Code available: N/A
Filename : N/A
URL : N/A
--------------------------------------------------------------------------
Description :
```

The Gamer's Die roller is a little thing I am putting together as my first Stamp Project. The Roller allows cumulative rolls of n dice up

to 256 sides, so long as the sum does not exceed 99,999,999(!)

It uses two 74HC161 4 bit counters cycling at 1MHz to draw random numbers off of. Input is achieved via a Grayhill model 38 keypad and a 74C922 keypad decoder. Display is on a Siemens PDSP-2111 8 character smart display (5x7 LED characters) fed by two 74HC164 serial to parallel shift registers cascaded so I can use Shiftout to feed 16 bits of control + data off of 2 pins.

The code is very simple, the most exotic part being the random number generation. In a nutshell, it is:

```
Begin Loop
S = 8 bit number drawn from the counter (random)
if S < (255/N) x N (integer divide, N is number of sides on die)
exit Loop
End Loop
```

This gets (pseudo) random numbers whose average is not skewed downwards by the counter's max of 256 (i.e. a 100 sided die is not affected by the extra 56 in the count maximum)

Using gamer's dice notation, (5d6 = sum of 5 six sided dice, 3d10 = sum of 3 ten sided dice), the user can input whatever combination they wish, including just 'd6' for one six sider. The keypad I have has removeable keycaps with legends, so I have 0-9 plus 'd' and '=' on them.

As noted earlier, since I am using an 8 bit counter, the maximum die size is 256, although that could be fixed easily by sampling two, three or more times for each die.

Anyhow, that's it. When the code is done and debugged, I'll be happy to e-mail it to any who want it.

```

Title : Switching Sytem [# 018]
==========
Date : 960109
Author: Alexander Avendano
E-mail: aavendan@aros.net

Stamp model : BS1-IC Module
Code available: N/A
Filename : N/A
URL : N/A

Description :

I'm almost finishing a Basic Stamp Based Switching System (Small
Phone system) which I consider very usefull for small companies that
cant'n afford other brands. This is designed with a host computer
which will have a vox-mail and all the functions like big ones to
choose. I'm using BS1-IC's for the extensions process right now.

As soon I have complete it I will give the code away for small
Intelligent Switching phone system up to 2 Lines and 4 Extensions
using the L.C.D serial circuitry for information display. I forgot
to mention that the computer (Host for many processing functions)
will be running under Windows 3.1 and Windows 95, making this way a
usefull computer not only for the phone system but for ithers
application at the office.

Please be free to send me E-mail, about any suggestion.

==========
Title : Door Entry Card Reader [# 019]
==========
Date : 960110
Author: Ed Buckley/J J Barbarello
E-mail: ed@milinst.demon.co.uk

Stamp model : BS1-IC Module
Code available: YES
Filename : N/A
URL : N/A

Description :

Stamp 1 based version of the Card Reader article by J J Barbello as described in the August 1995 edition of Electronics Now. This version uses the Stamp 1 as a local controller determining the card number and deciding whether or not to allow door opening. Optional serial comms back to a master controller and optional local message readout using an LCD Backpack.

Lots of scope for further enhancement/experimentation. Circuit schematic and listing available.

==========

1.5 Credits and other things

Credits should go to all of you who makes this list possible I hope it suffices to say "Thank you to all who have contributed to L.O.S.A - we all appreciate it."

Special thanks to all of you at Parallax, Inc. who makes and support this great products !

If there is anything you think I've missed (or spelled wrong <g>) I would love to hear from you so we could make this list even better.

You could reach me at the following e-mail address: cj@algonet.se

Stay tuned,

/Christer

I have a few 12V (10 to 14V) to 13.6V (+- 10% adjustable within
a small range) 1.7A continuous (2.7A peak) DC-DC converters that
I plan to use for battery charging (submersible video power packs etc).

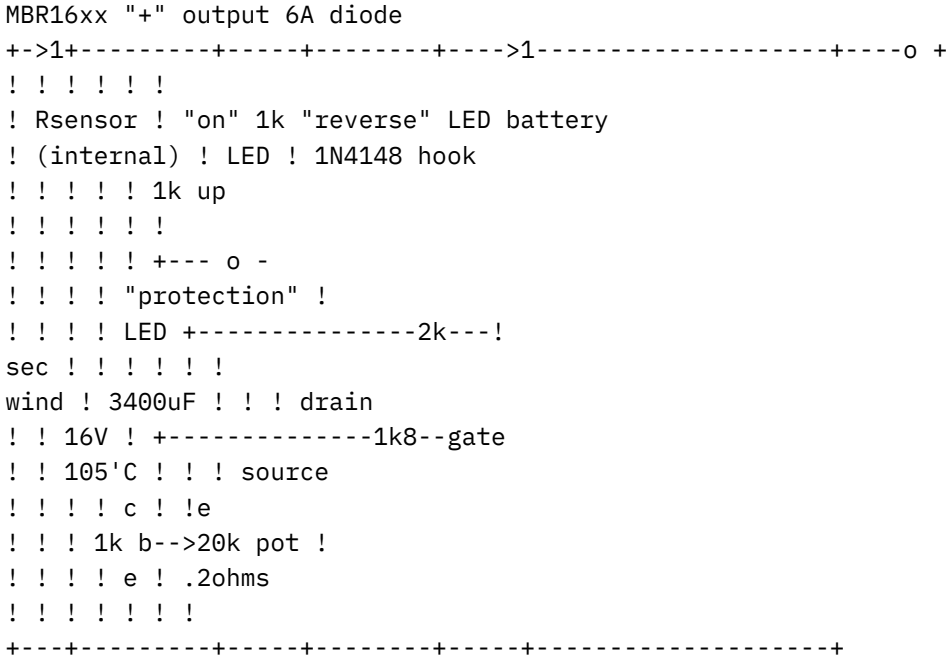
Works well but in my application polarity protection is called for.
(This might not be needed in a permanent installation).

So I put a diode or rectifier bridge on the input but have
been pondering how to protect the output made up of a
secondary transformer winding and one MBR16xx diode.
This posed various problems. I'm open to suggestions.

My current idea is to use an N-ch MOSFET in the
ground leg to the battery being charged. I put a .2 ohms
resistor in the source leg ("source degeneration") and I
connect the battery to the drain terminal. I feed the gate
from the "+" output of the DC converter and protect the MOSFET
(and thus xformer and MBR diode) against overcurrent (> 3A)
by sensing the voltage over the combined MOSFET (0.12 ohms and
Rdrain 0.2). This signal is voltage divided in a resistive
ladder and fed to the base of an npn bjt which shorts the
gate to ground if the base goes above 0.65 V or so.

Various resistors limit the branch currents and LEDs
indicate charger "on", "reverse polarity" and "overcurrent
protection". This last attempt managed to keep the voltage
over the MOSFET to a small value even in protect mode which
means I hope to get away with the IRF511 at radio shack.

Commenst very welcome if others have pondered similar
problems.



john

489. Need Novatel 8305A cellphone info badly

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-18 00:00:00 UTC

Well, here I go again, I've been looking for this information for some time now and hopefully SOMEONE has SOMETHING.

I have a few Novatel model 8305A cellular phones that I wish to convert over to 900MHz. They are black, square, about 10" x 10" x 2".

At the very least I need a schematic, but full service information would be nice too. I understand that there was a Novatel Amateur Radio Club at one time and they did just this, converted them over to 900MHz for packet.

Any info would be appreciated and I of course will pay costs of copying and shipping if necessary.

Please reply via e-mail... ka1kjz@ix.netcom.com

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.amateur.misc,rec.radio.amateur.policy,rec.radio.amateur.space,rec.radio.shortwave

I am looking for information about cases involving legal disputes between local government, city to be exact, and private industry. I am having trouble getting a local township to agree to let me raise my business tower to 500 feet. They have been stalling me for over a year now. Any information would greatly be appreciated.

Please either post information under this article or preferably e-mail me at 'dragottj@milwaukee.tec.wi.us'. Thanks.

>the question is this: Should I replace the 20 amp breaker in the panel
>with a 15 amp unit?

1. Yes, it should have been 15 amps in the first place.

2. Make sure your work conforms to your local electrical code.

3. Read Chris Lewis's excellent electrical wiring FAQ from sci.electronics
ftp://rtfm.mit.edu/pub/usenet-by-hierarchy/sci/electronics

4. The number of outlets and breaker size have little to do with each other.
You can overlaod a circuit from one outlet.

5. Wire size has everything to do with breaker size. This is so that the
breaker will trip before the wire overheats. For average situations:
Gauge Amps
14 15
12 20

In this state, wiring can be legally done only by the homeowner or a licensed electrician, and a state permit is required. I think that this is the rule in most other states. If you ever have a fire and the insurance company discovers the wiring wasn't legally done, they might not pay.

Cheap depends on your ability to find resistors. I once made a dummy load by paralleling thirty 1500 ohm 2 W carbon composition resistors. I connected 10 in parallel side-by-side with a 12 guage (or so) wire along the grounded side. I then took three sets of 10 and connected them altogether, in a "Y" configuration, along a common #12 wire which went to the center of a coax connector. The three wires at the other end of the resistors were connected to the body of the connector. It worke OK at 50 MHz, although it had some noticeable reactive component at the frequency. These resistor now run $2.69 each with minimum purchase 25 from Newark. So if you go this route it will only be economical if you can find a cheap source of resistors. Of course you can use differing numbers of resistors, different resistance, differenct wattage. The point is if you need a load at 50 MHz or below you can get away with a lot. Probably a smaller one might even be adequate on 144 MHz.

Or, find a Heath Cantenna somewhere. They were the size of a 1 gallon paint can and would meet your requirements without the oil, depending on what frequency your are planning to use.

>scale.

I also had to do that awhile back. The software was cumbersome for this purpose, but it did get the job done. The program I used was Micrografx Designer, an illustration program similar to Corel.

First, I drew an outline of the meter face and marked the exact location of the pivot point of the needle. Next, I drew an arc across the face and positioned it where I wanted the scale to be. The center of the arc was about four or five inches below the pivot point of the meter, and I positioned it so that at the midpoint, the needle would extend past it by about 1/4".

From there, I drew a vertical line from the needle's pivot point to a point 5/16" past the arc. Next, I duplicated the line several times, so that I had one line for each gradient marker that was needed. All the lines were lying directly on top of each other in the drawing.

After that, I used the "rotate" function to rotate each line a specific number of degrees, pivoting them at the bottom. Alternately, you could use the rotate and drag function to move each line exactly where you want it, in case the scale isn't linear. Finally, I drew a white oval with no border, moved it on top of the lines, and used it to mask the lower portions of the lines so each would appear to be only a short marker across the scale.

There are probably a few different ways to get this done, but that's the method I used. If anyone knows of a quicker technique, I'd be interested too. Apparently, meter manufacturers use dedicated software for this.

Incidentally, you can draw the lines so they are either perpindicular to the curved scale or parallel to the pointer, but not both. This is because the curved scale isn't centered on the same point as the needle and is also drawn on a larger radius. If you examine a meter while the pointer sweeps the scale, you'll see that the pointer extends much further past the scale at the center than it does at each end. Anyway, in all the meters I've seen, the markers are parallel to the needle. This keeps the pointer positioned correctly on top of each marker as it moves across the face.

As Jim says below, you probably can't doing cheaper than buying one
already made.

You don't say what freq you're interested in. I did a similar
thing to Jim for 10W using 1W resistors, howwever with a little
more effort I got the thing to have little reflectance at 2m (SWR <1.1
couldn't read it). I used a design out of one of the RSGB books (great
books guys). I used a BNC connector and the thing was a cylinder
with the resistors being the walls of the cylinder and two copper
discs about 1.5" diam, being the end plates. I drilled holes for the resistors
around the circumference of each plate and put a BNC connector
at one end. The next bit is a bit tricky - you have to join the
center pin of the BNC connector to the plate at the other end of
the dummy load. The conductor you use has to have a diameter such
that the characteristic impedance of the piece of "coax" formed by the
outer wall of resistors and the center conductor is 50ohms - I used
a piece of brass tubing about 3/4" in OD (from what I can remember)
and cut a hole in the copper disk at the far end of the dummy load
to fit. There's one more wrinkle - you;re going from coax the size

of a BNC connector to coax with a much bigger diameter. The step
there will appear to be a discontinuity unless you get it right.
I didn't know how to do it right and I guessed that gap from the
center pin of the BNC connector to the smaller copper plate I made
to join onto the brass tubing, should be about the same size
as the gap between the tubing and the resistors. As I said at
2m the thing was perfect.

the MAX713 does not do a "reflex charge". Did you make up your own design
for a charger or did you base it on the data sheet example? How well
does the chip work? What types of cells are you charging and how fast?
If you have a nice design, could you post a schematic? ICS has a web site
that contains the data sheets in postscript format if anyone else was
interested >>> http://www.icsinc.com/products/pwrindx.htm

I am upgrading my old 386dx40 system to a Pentium system. In the
process
I have many usefull parts to try to peddle. The items are listed below
and priced to go fast. They will be sold first come first serve.
Get back to me fast or make offer if only kinda interested.

1 meg 32 pin simms $20 each Have 4

IO card providing 2 com ports $3

80mb scsi hard drive as is $7 1 meg segment on hd is bad, but I
just partitioned it off and use the other 79 no problem.

Samsung data monitor, color cga with vga adaptor plug $15

XT computer only no monitor or keyboard all else there.$18 or make
offer!!!!!!

SCSI controller cable. 3 feet or so long. $3 ($5 to $15 new)

brand new dual floppy drive. 5 1/4 and 3 1/2. Fits in 5 1/4 size bay
Just one floppy sells for$45new. This went $120 new asking $55

2 working printers. Both have manuals and work fine.
Toshiba Expresswriter 420
Star SG 15

I will sell them for $40 each or both for $70

Also have

D104 microphone $30
40ch Pierce Simpson cb mobile set $15
several 23 channel cb mobile sets $7

Jack, Fairchild is gone...I believe what was left of them got acquired by National Semiconductor a couple of years ago, and I don't think you'll have any luck w/ National Semiconductor either.

Taking a brief look in the Cross-Reference section of a colleague's 1982 Fairchild Linear data book, I don't see any competitor's device crosslisted to a uA757, which would suggest to me that the 757 was a unique amp (and would support your inability to find a SK/ECG/etc. equivalent).

About the only thing I can offer you is a copy of the relevant pages on the uA757 from my co-worker's Fairchild Linear book, in the event you can't get any OEM replacements. E-mail me if you need the copy.

Good luck -

TGB

Im looking at building several QRP projects, they all call for different size wire on the torroids, usually #26,#28,#30 is there a formula for figureing out different gage wire substitutes?

I dont mind buying a spool or two of the different sizes but if the spec calls for 30 turns of #28 on a T60-6 can you put more or less turns of #26 and get the same results. Why the different sizes?

Somebody clue me in....

Thanks,

Tim, ka8ddz

Well, just calculate the inner circumference of the toriod, and the diameter of the wire. Of course, consider that the effective inner radius is about one wire radius less than the actual circumference...

If you buy some Amidon cores, they include a lot of data, including a chart of core size vs. wire guage capacities.

The wire size won't affect the inductance significantly. Inductance depends on the particular core, and in general, for a given core, the inductance increases as the square of the number of turns: double the number of turns and the inductance multiplies by 4. That's true for air-core coils, too, if you wind the wire in the same space..same diameter and length, but more turns (of smaller wire). But for toroid cores, you wouldn't want to try to put more turns through the center than will fit. For RF work, general practice seems to be to keep it to a single layer, so you'd want to go smaller in wire size if the original had things packed tight around the core already. If you get an information packet from Amidon, it will probably have a table of number of turns of various wire sizes versus core size.

In general, you want to use the largest wire you can for a given core and winding geometry (i.e. single layer), to keep resistance low and Q high. But in air-core coils at RF, it's usually important to space the turns apart from eachother to keep distributed capacitance under control.

>
> Somebody clue me in....

It's probably the case that the wire sizes are different so as to ensure that the wire diameter used is at an optimum value, to get as high a Q as possible, for a given number of turns. The inductance basically depends on the number of turns, rather than the wire size, so just use the same number of turns with the different wire, and you should be OK. The different Q probably won't make any difference that you'd notice, on HF, anyway.

Wire size does matter, of course, if you are need lots of turns, to avoid overlapping turns, which increase the self-capacitance and affect the Q quite a lot (I think).

Perhaps I missed the first part of this thread, but when I was in grade school, one of our science projects was making a battery out of an orange. We took pennys (copper) and nickles (zinc I think) and pushed them into the orange 3/4s the way down, alternating between them (penny, nickle, penny, nickle, penny, ect.), being very carfull not to let them touch...but getting them as close as you can.

After going half way around (dont go any farther...it will slowly decrease the voltage), we were able to light a small lamp. I cant remember what voltage we got...but it did work...a basic 'acid' battery. Remember to end one side with a penny, and the other with a nickle (polarity).

I also remember seeing a potatoe powered clock somewhere in a catalog...but cant remember where, but do remember it worked on the same principal.

Take care all, & 73.

Well, just calculate the inner circumference of the toriod, and the diameter of the wire. Of course, consider that the effective inner radius is about one wire radius less than the actual circumference...

If you buy some Amidon cores, they include a lot of data, including a chart of core size vs. wire guage capacities.

From: ai657@freenet.toronto.on.ca
Message-ID: <DLFLFK.B11.0.queen@torfree.net>
Source record: 107942

I need some help repairing an Eddystone EC-10 SW rig.
I have the manual and have tested the transistors using the
figures in the "Voltage Analysis" section.
All seemed close to the values quoted except TR4 & TR5 (IF Amp).
TR4 should be 0.87v (E) 1.15(B) 5.6(C) but is 0.36(E) .64(B) 1.71(C)
TR5 should be 0.40v (E) 0.70(B) 7.5(C) but is 0.05(E) .28(B) 0.28(C)

I am not well versed in electronics repair and am hoping that someone can
put in the right direction. Should these transistors be replaced? If so,
would they be commonly available here in Canada. (OC171) If not, then
what would be a suitable substitution? I've noticed that these
transistors have 4 leads. The fourth is labeled "S" and always goes to
ground. Is this akin to grounding the case of the transistor?
Looking forward to hearing from anyone who may be able to help.
Please email. Thanks in advance.
Paul.

Instead of putting BFO (Beat Frequency OSC.) in the radio and "BEAT" it against the 455khz IF, you can set a 455khz OSC. next to the radio, and you'll hope that it is a very stable RF generator,oscillator ect., and "BEAT" the oscillator against the signal being received in the 455khz IF. Same thing as a BFO. The IF strip in a radio is just a receiver at an IF frequency, and if not to will shielded, it will also receiver your external RF oscillator.

I have done this many times. But you'll find the dial on the external RF oscillator very touchy if not designed to be use in this way. Like breath on it, and it will change.

I've seen several people interested in doing their own meter faces
and just wanted to say that it is not that hard. I had an article
published in April 1995 Electronic Now describing the technique that
I use. Works great. One reader even took my basic program and made
it menu driven so that all you do is give the meter physical dimensions,
the way you want the meter laid out, and how you want it labeled, then
presto, it comes out on any HPGL printer.

For $5 (to cover envelope, disk, and postage) I'll mail you a copy.

Robert Everitt Heiss (rheiss@tuba.aix.calpoly.edu) wrote:
: The UHF hybrids sound interesting, and I am also looking for HF
: transistor (MRF485, etc.) alternatives to Motorola. So, want to
: share any opinions on Mitsubishi? What data books or app notes
: should I ask for? A distributor which accepts small credit card
: orders would be nice to know about, too. Thanks.

Mitsubishi VHF and UHF hybrid power modules are used in quite a few
of the Big-3 VHF/UHF rigs. Reliability is not very good, but I'd say
this was more a matter of application rather than the hybrids themselves:

How to kill a power amp hybrid:

1) put lots of thermal compound under the thing and really tighten
the mounting screws at the ends. The aim is to use the pressure
under the centre of the hybrid to bend its copper plate and split
the alumina substrate inside. This is a nice fault as the
fractured part often works fine when cool, but stops working when
hot. Think of it as a way to limit over lengths.....

2) Don't have any form of thermal shutdown sensing the temperature
of the thing, be a bit stingy with heatsink size. Temp rise on
a hot day will crack the substrate. Ragchewers or folk who stack
books on their radios will suffer.

3) Why not try a fan-cooled heatsink with no over temp shutdown?
the fan will eventually wear out and allow the module to stew
itself to death. Try a thermostatic fan so the operator won't
notice when it dies......

Seriously, the modules could have been better designed to avoid the
first problem, but if you're sensible, they're OK.

Put on some form of over temp shut down and you'll have excellent
reliability. Mitsubishi have been involved in RF power devices for a
long time and can be considered to be as trustworthy as anyone.

Have fun
David GM4ZNX

ps with a reasonable stereomicroscope and soldering iron, I've
repaired failed modules quite successfully.

It often doesn't. The impedances across which it is expressed will determine whether it will flash over there or not. The transient, for the case of lightning, is a current pulse of up to 18,000 amperes, but of very short duration (so energy is low). It doesn't take much of an impedance for that pulse to translate to a very high voltage (a megavolt is not uncommon), which can then flash across ordinary insulation or air gaps. The purpose of transient suppressors is to give the pulse a defined and controlled place to discharge rather than depending on chance to allow it to flash somewhere unpredicted.

That's a lot of current, it almost sounds like a direct hit on the outlet!

Are you saying the MOV you were describing would protect equipment from damage with that type of hit? Perhaps they are worthwhile!

Can you run a model of the MOV you described in a typical line input circuit to see what happens?

The TL 442 would make a good alternative to the MC1496.

Made by Texas Instruments, this chip requires a much lower component count.

It has balanced 50 ohm and 600 ohm inputs and is ideal for product
detector circuits.

602-961-1382

There are several grades of duroid laminates. The original grades were
5870 and 5880, they are PTFE filled with non-woven glass fiber. They
have dielectric constants of 2.3 to 2.5. There is a similar product called
6002 that is PTFE filled with Silica powder, it has a better dimensional
stability and less change of dielectric constant with temperature.

Thre are also 6006 and 6010 grades with dielectric constants of about 6
and 9.2. They are PTFE filled with other ceramic powders.

The circuit board fabricators that work with PTFE laminates have some
specialized fabrication methods, but if you don't need plated through holes
you could probably use them with few problems.

538. ANY INFO ON AM912A/TRC?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-20 00:00:00 UTC
From: Gary Davidson <reporter@sparc1.castles.com>
Message-ID: <4dplgm$k9h@miwok.nbn.com>
Source record: 107956

I have a VHF RF anplifier deck military surplus, model designation AM-912A/TRC. It covers the frequency range 100-224 M.C., using a single 4X150A in the final. It is an RF deck only, no power, metering, etc. It uses a cavity tuned grid and plate circuit, is all VERY heavily silver plated, and seems to be exceptionaly well engineered. It is about the size of a TS440 HF transceiver.

My question is: If I substitute a 4CX250B in the final, and build an appropriate power supply, what sort of efficiency could I reasonably expect from this cavity tuned circuitry compared with what we amateurs normally use at VHF frequencies? Is cavity tuning more, or less efficient than some of the copper pipe or strip type circuits.

Perhaps someone out there recognizes this device and can offer some helpful info?
Thanks, and 73, Gary, KJ6Q.

> Thanks,

> Tim, ka8ddz

Tim,

I did some measurements years ago which show that inductance and Q
change very little over a few wire gauges on common toroid cores.
There's likely to be a greater variation in toroids due to tolerance
of the permeability and mechanical dimensions than you'll see by
changing the wire size a few gauges. The wire size is usually
dictated by what the author has on hand. Avoid using wire so large
that it won't conform to the core, but otherwise use what you have,
don't change the number of turns, and you'll be o.k.

73,
Roy Lewallen, W7EL

>spec calls for 30 turns of #28 on a T60-6 can you put more or less
>turns of #26 and get the same results. Why the different sizes?

For a *space* wound coil on a core, the size of the wire is determined primarily by the amount of current it must handle. Thus for higher currents, larger gage wire is chosen. (Note for RF it is skin effect resistance that counts here.)

For a *close* wound coil on a core, it is the number of turns that will *fit* on the core that determines gage. Obviously, more turns of wire can be put on a given size core if the wire is of smaller diameter. (Multilayer and scramble wound cores are grossly different than the single layer type we're discussing of course.)

If neither of these limits is a concern, then it is only the number of turns (and the core material of course) that determines inductance, not the wire gage. (There are, usually minor, factors beyond the number of turns that determine final inductance. The spacing of turns affects the turn to turn capacitance, so spreading or compressing turns on the core has the effect of varying effective inductance. Different gages may allow *room* for more or less of this spreading and compressing.)

Air core coils have different constraints having to do with length to diameter ratios, flux leakage, and the like, which complicate the picture. You can largely ignore these issues with toroids as long as you use the specified core.

The OC171 was made by Mullard (part of Philips) something like 30 years ago. I used the similar OC170 in a simple reflex Rx in the 60s. You'll probably have trouble finding them in Canada. If you need to replace them, I can think of one or two places here in the UK that *might* have them, like Cricklewood Electronics. The 170 was an RF amp, and the 171 an IF amp, as I recall. Both were germanium, of course. The 4th lead was a screen and was connected to the case.

Does anyone know how to measure the permeability/loss of a toroid core (without too much difficulty !) ?
They are difficult to get locally (I usually have to order them from Amidon in Cal.) but some surplus stores in Toronto have a wide assortment of bins of unmarked toroids. It would be a nice cost-effective altenative to having to order new ones if we knew what we had sitting at our doorstep.

A friend on a local BBS originally posed this question to me...
I couldn't really answer him ...I am also curious !
I thought that winding some wire onto them and taking impedance measurements at various frequencies may work but how does one accomplish this ?

Thanks..

>years ago.

Great idea. I built one last year and had it calibrated. Flat (+/_ .4 dB)
to 2.5 GHz and then down 1.8 dB at 3.0 GHZ. I used a commercial barrel attn
(8 dB) on the output that was spec'd to 2 GHz so suspect that was the reason
for the quick rolloff.
>
>I!m too cheap to buy a NoiseCom diode, and I!d like to try a 1N21

>In general, you want to use the largest wire you can for a given core and
>winding geometry (i.e. single layer), to keep resistance low and Q high.
>But in air-core coils at RF, it's usually important to space the turns apart
>from eachother to keep distributed capacitance under control.

Addtional note: Yes you can use a smaller gauge of wire but the turn/turn
capacitance will change and hence the inductance per same number of turns will
change somewhat. Also turns spacing, how close the winding ends are, and in
the case of multiple layer things really get complicated.

FYI:

I've used Amidon's design liteature for toroid/ferrite winding info and found
it to be fairly accurate.

>this ?

What you want to do, Hugh, is find the proportionality constant between the number of turns and inductance. Wind the core with several different numbers of turns, and measure the inductance for each. You can use an inductance meter, or just resonate the coil with a known capacitor and use a dip meter. Now graph the inductance versus the number of turns and devise an equation to fit the curve. The inductance should be proportional to the square of the number of turns, with the proportionality constant being the unkown you are trying to find.

L = k * (N)^2 or k = L/(N)^2

To determine the suitability of the material for various frequencies, excite the coil at those frequencies and measure the Q of the coil. Actually, the size of the proportionality constant you found above should already give you a clue. A large proportionality constant indicates a core suitable for low frequencies while smaller proportionality constants will indicate the core is suitable for increasingly higher frequencies.

>Paul.

The 'S" is for SHIELD, normally tied to ground. Based on the voltages
you described between the BASE and EMITTER I would conclude these
are old GERMANIUM type transistors...hard to come by. Also, based on
your measured values, your collector values are quite low from what
they shoould be.. I doubt the transistors are the cause but another
stage (like AF AMPLIFIER transistor) shorting out that bogs everything
else down...or a resistor or RF CHOKE that feeds your IF AMP. Very
rarely do CLASS A amplifier stages operating at low DC levels just
die, I would look at the HI-POWER stages...AF AMP, POWER SUPPLY
and REGULATOR first......

Hi. My dad is a Ham operator, and asked me if there were some inexpensive way to have incoming Morse code automatically translated and displayed on a CRT. Since I know nothing about Ham radio, I thought I'd post here. I'm sure what he wants to do must be possible; don't know about the inexpensive part though. If anyone can help us out I'd appreciate it. I'd prefer that responses be sent in private email, as I usually don't read these groups.

Thanks in advance.

554. Need Help Indentifying Transistor

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-21 00:00:00 UTC
From: thom@newshost.li.net
Message-ID: <4du6dd$q9j@linet02.li.net>
Source record: 107875

Hi and thanks in advance for your help,
I am in the process of building a keyer and it calls for a 2N2222 transistor....In my junk box I've come accross several 2N2222A's. First off, Am I right in making this assumption that these are OK to use?

The transistors I found are in a metal case wich and came in a package which says NPN TO-18...So I guess TO-18 is the case type.

Its a metal case with a small tab coming out of the bottom...I see similar cases called TO-18 in the 1996 ARRL Handbook so I'm OK on that score, I think.

Anyway my question is how do identify the leads? If I look down to the underside of the transistor and position the tab at 4 O'clock, the 3 leads are at 12, 6 and 9 O'clock.

If you can can tell me which leads are the emmitter, collector and base I'd appreciate it...more importantly, if you could tell me how to figure it out, myself, I woun't have to bother you the next time.

As I said I look in the Handbook, got close but couldn't find the answere.

Thanks for ypur help

Tom

I understand that there is a device that can be connected in series with your modem or phone that inhibits off hook when another extension is in use.

Here in Seattle it is supposedly available at Home Depot (a home hardware store). I think it is a thyristor type device that turns on when the voltage across it is larger than some preset value (20 volts maybe). Of course, if the voltage is somewhat low, then the line is already in use and it won't trigger. This is only a guess as to how it works, but hearing that it was a two terminal "diode looking" device, that's probably correct. Also, supposedly one of these things had an LED in series also. I would think though that you'd want to put a capacitor in parallel with that for less attenuated audio.

>Regards, Wes -- N7WS

Wes,

I test VCO's, amps, etc in quantity (more than most government/aerospace contractors probably make in a lifetime) and the parts to be VERY repeatable and tight in tolerance to make it through testing without rediculously large limits. I'd venture that a large portion of the paperword no one wants to do is Davis-Bacon boiler plate and the like. That, and stuff that overspecs the part to the degree that you CAN'T make a part without tweaking the life out of it. But for commercial/consumer apps, repeatability and predictability of the product are key. The customer isn't gonna stop to tweak each of >50k units they're gonna ship, but they won't take substandard performance either.

So I'd disagree that using commercial parts necessarily means 2nd best. On the contrary, a designer should be able to optimize a design with a highly repeatable product.

73,
Mark

Subject: Radio circuit required

I'm hopeing that someone could point me to either
1) An Internet site with circuit diagrams
2) A book with appropriate circuits
3) A person who could design an appropriate circuit
4) A company that sells what I want.

What I need is a small radio that fits the following specs -
1) Any frequency (preferably an unlicenced peice of spectrum)
2) Digital transmition of 500 bytes per second
3) 200 meter range under bad indoor conditions
4) Digital tuning
5) Runs on 4-6 volts
6) Low power consumption
7) Rapid startup/shut down for the transmiter
8) 10 channels

If possible I'd like the following improvements
1) 1000+ bytes per second
2) 500+ meter range
3) Run on 3-6 Volts
4) 30+ channels
5) Able to easily transmit analogue (voice) signals

Thanks for reading this far.
I'll appriciate any help anyone can give me,
Ian Simcock.

My fears involve long term effects such as problems with moisture and plastic packaged ICs. This isn't exactly my area of expertise, however, in my department, we have materials people, chemists, and other components engineers that share my concern. I realize that some environments, particularly automotive, have conditions that may be worse than mil spec requirements. However, if you store your car for ten years in a bunker then ship it to Saudi Arabia and store it for a while at 140 degrees F and then ship it to Alaska and store it there for a while then take it out and try to start it with the first turn of the key, what happens? You probably will have six sigma (latest buzz word) repeatability; it fails 999,997 times out of 1,000,000.

On a not too related subject, but one brought on by a not to well thought out edict:

We have also been forced to eliminate the use of oxygen-depleting-chemicals (ODCs), such as the defluxing agents used to remove rosin flux. So, we use acid fluxes and water-based solvents. Of course, we are using surface mount components too. What are the long tern effects of less than perfect removal of the flux trapped under the components in moist environments. Your guess is as good as mine. But this is progress :-)

>Airbag. n. 1) An automotive accessory designed to explode on impact.

ALL of our products are designed to explode on impact.

(a) If you can't take the time to read the newsgroups you post in, don't post. Asking for email answers in a newsgroup wastes all our times in reading.

(b) It is a function of the thickness of the copper on the board. For "one ounce" copper board, I've generally used 15 mils of copper width for each 100 mA of current and never had a problem. I'm sure when you get to current measured in amperes this rule of thumb breaks down, but for medium currents (less than an amp) it has always been OK for me.

OK, I'll give it a try. Measuring Permeability, Pb, isn't too
difficult but it requires measuring inductance. I use a little unit
from Jan '81 QST that, in turn, needs a frequency counter. So if you
have these then the easy way is probably to measure the dimensions of
the core and find it in the Amidon catalog. Then wind enough turns
to cover about 3/4 of the core; with ferrites probably about 10 turns
but more may be needed to get a good inductance measurement with
powered iron cores. Measure inductance L in microhenries. Then
calculate the ALratio by: Alratio=L(uH)x10000/N• where N is the
number of turns. (If you measure inductance in millihenries use:
ALratio=L(mH)x1000000/N•) You can then go back to the Amidon catalog
and find the type of core closest to your unknown. .

I f in Amidon you can't find a core of the size you are testing you
can calculate Pb by: Pb=L(uH)/(.0319xN•xfactor) where:
factor=Hx(OD-ID)/(•x(OD+ID)). H is core height, OD is outside
diameter and ID is inside diameter.

The numbers you will get will not be exactly the same as the Pb in
the catalog but the material types are sufficiently different that you
can make a pretty good guess. (at least for the ferrites.) To
identify powered cores exactly you need the loss data.

Loss data is more difficult to get. You need to be able to measure the Q of the test windings. I won't attempt to get into that here.

Good Luck OM, 73 Clay, KF4IX

3 feet? I could mail him some but the postage would exceed the
value of the twinlead. We have found 72 ohm twinlead to be
fairly difficult to locate and when we finally did we bought a
spool. For short HF uses many varieties of common 2-wire AC
"ZIP" cord closely approach 72-75 ohms impedance. Perhaps that
would work for his application.

John,

Of course inexpensive is comparative, but you should be able to find an XT or 286 PC with monochrome monitor for under $100.

There are 2 or 3 at least shareware programs that are a $10-20 registration that will do this fairly well. The first that comes to mind is the PRO-CW, at least I think that was the one, it included a schematic for the interface also. I played with it for a while, and it worked if someone had a clean fist or sent with a keyboard. I probably still have it somewhere if you can't find it anywhere else. I also think it is on the QRZ CD or home page also.

Good Luck

And remember when you make the test, you should make it at several frequencies.

The permeability of the core is different at different frequencies. At some frequency the eddy currents will make the permeability slope down rapidly.

I have invented a kit that allow you to tune in CW/SSB with two SW AM radios. I have enjoyed SSB since a year ago. I have to return my Radio Shack DX-390 to the store because of its poor quality compare to my receiver. I have bought many AM SW radio from thrift store since than and all of them work great, in fact, I should say excellent.
I am willing to share my invention with everyone that does not afford to buy those expensive receiver and have no time to build complicated things. My kit just take you 2 minutes to hook up these two radios and ready to enjoy years of fun in CW/SSB. No modification and no screw driver or soldering required. All you need is $5.00 to cover the cost of shipping and cost of the parts for the simple kits and instruction. email me at hts@thor.net for more info.
I have 6 CW/SSB receivers now at my station. fun! and cheap but effective.

I did this when I was a kid, tuning in hams on a SW receiver
before I got my ham license. You don't need a crystal oscillator,
any oscillator will do and I just draped a wire from the oscillator
into the back of the box of the radio - no solid connection.

The discussion of grapefruit powered whatever reminded me of an ad I saw in a trade rag five, maybe six years ago for a company making single board microcontrollers. The add was full color, back back spread featuring their board connected to an exercise wheel with a gerbil running in it. It looked like the had replaced one of the exercise wheel's bearings will a little dc motor (generator).

Source record: 107913

The 814 is a 65w plate dissipation beam tetrode. It requires 10v @3.25 amperes for the filament
and 300v for the screen. Typical operation to 30 MHz in class C would be Plate Voltage 1250 to
1500v @ 150 ma plate current. Grid drive 10ma @ -90v. I believe that the 814 may have been used
in the Hallicrafters T-20 and Collins KW-1 transmitters just after WWII. It is useful as a screen supply series regulator, or as a power amplifier in medium power applications. Pinout is
1&5 filament, 3=control grid, 2=screen grid, and 4=Beam Forming electrodes.

>73 Tom

I hope I am happy when mine arrives. As for the short and thick, that depends on the signal in RF. Some microwave circuits depend on "controlled" length and thickness, though better called width here, since thick is the depth of the copper clad. In my designs (I design electronics for a few paying customers),

width is important in power supply to reduce I-R losses, as well as some key analog traces.

I will post as soon as I finish building my tuner to let others know what I think of it.

Try 11 trifilar turns #14 formvar or TFE insulated wire. Connect the turns in series. Ground at
the far end of the first turn. Balanced output at bottom and 2/3 tap. Unbalanced feed at top (to
ground). Generally a 2.4 " dia Q-2 material 1/2 " thick is used, but your 1.125" thick material
probably won't saturate at 1000w.

Just a word of warning! You can just divide up an arc into equal segments and get a nice looking scale but it is likely to be inaccurate. To do a good job you should measure a bunch of angles versus current and construct a smooth scale by interpolation on the measured points (or measure ALL the places where there are to be scale divisions!). I would suggest 10 or so measured points. The problem is that the magnetic fild is not strictly uniform over the region used by the meter coil. There are various reasons for the nonuniform field but the end effect is a nonlinear scale which is dealt with in different ways by different commercial makers. One technique is to have several scales with different sorts of common nonlinearities built in. Then pick the one most nearly matching the movement. Hewlett Packard had a machine which could follow the needle as different currents were applied to the movement and construct a very nice scale from the measurements. (I suspect writing the scale onto a film.) This scale then belonged only to the tested meter.
For one time only users, doing it by hand is not a bad job. I recently made a scale and the result was good (without any computer but working on an enlarged master followed by photcopy size reduction.)

My boss spent all night measuring "real" varactors and every
other kind of diode he could find. Results showed green LEDs with the
highest Q (lowest series R) of all. Cap ranges around 10 to 5 pF and
useable to a reverse bias of 10 to 15 volts.

I failed to make the connection between the varactor number given
and the requirement for any real power. LEDs *would* be limited to the
milliwatt range. We used them in VCOs and VCXOs.

> range, centered in the VHF and UHF ranges, and finding low capacitance
> varactors with good Q has been difficult. But I also suspect the green

Probably a better way to create meter faces and other scales is to draw them by a simple computer program. Borland's Delphi product makes drawing and printing Windows graphics under program control very easy, and you can calculate the spacing of the lines and so on if you know your graphics math.

Just a thought.

You better take a look at the effects of the mismatches between a handful of
these things. The specified 1.6 in and 2.0 out SWRs look like cascaded
ripple trouble to me. I have only the tabular data in front of me but I note
that the figures are "typical". Your mileage (and gain) may vary.

>Maybe I'll try a MAV-11 MMIC as the final amplifer, as it has a 18 dbm

610. Dry Cell sizes

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-23 00:00:00 UTC
From: mack@mails.imed.COM
Message-ID: <9600238224.AA822443981@mails.imed.com>
Source record: 107829

There has been a thread on Ham-Homebrew about how to put a "blank" AA dry cell in a pack when going from Nicad to Alkaline. This reminded me of something I saw when putting the kids' toys together at Christmas. Many of the toys use a reducer and a AA cell where there is intended to be a C cell during normal use! These are found primarily on the toys that scream "TRY ME" to the kids. (I'm a big kid at heart and it drives my wife nuts. "How can I teach the kids not to touch when you do?").

So the moral is: if you have something that uses C cells and you need an emergency supply, you can wrap something around a AA and get a C cell.

>>MMIC amplifiers and use the noise with my spectrum analyzer to measure
>>filter response, etc, up to 2 GHZ. The noise hopefully should be flat
>>across the spectrum.
>
>How flat do you think that many MMICs will be?

Yes. I know I'm cheap and ought to use the NoiseCom diode, however I
haven't purchased one yet! I do have a few 1N21 diodes and I was
wondering the how they compare.

I figure I need to amplify a noise source of 20 ENR about 40-50 db to use
this as a broad-band signal source to use in lue of a tracking generator
for my spectrum analyzer.

The Mini-Circuts MAR-4 (8 db gain) only drops 0.2 db from 100 Mhz to 1500
Mhz, and drops only another 0.3 do to 2000 Mhz. If I cascade 6 of these
babies, I'll get about 50 db of gain, however any more and I'll exceep
the 1db compression. This would give me a flat noise source with less
than 2 db of dropoff.

Maybe I'll try a MAV-11 MMIC as the final amplifer, as it has a 18 dbm
max power, but it is not very flat.

Has any one had any experience with this sort of thing?

>WA1RHP

The 2N2222 is still available (in plastic packaging) as far as I know. And I've seen 2N2222s in TO-5 packaging, but I don't think those are made anymore. For metal can packaging, I believe you're correct that only the 2N2222A is currently produced. The main difference is that the A device has a tighter beta specification and is offered in the TO-18 cans.

The 2N2222 family is *the* generic NPN switching transistor, though the 2N3904 and 2N3906 are also very popular. For most uses, any of the generic devices will work.

: for a balun on an antenna project. I know very little of the project,
: but he does not have internet and I wanted to try and locate a source for
: him.

You can't realize this transmission line with twinlead construction.
For an impedance that low, the diameter of the conductors is greater
than the spacing:

s = center to center spacing
d = wire diameter

Zo = 276 LOG(2s/d)

Usually transmission lines using twinlead type construction have Zo
values in the *hundreds* of ohms.

You can still make a 72-ish ohm balanced transmission line, however,
if you use a different type of construction:

Take four (4) sections of RG-59 (73 ohm coax) of equal length and
run them in parralell. Solder all the shields together on both
ends. Now, connect the center conductors together in pairs.
Cable A and B should have their center conductors connected
together on both ends, and cable C and D should have their
center conductors tied together. You now have a 73 ohm
shielded *balanced* transmission line. I will try to render it
in ascii:

```
-----------------------------------------
-----------------------------------------
/ ---------------------------------------- \
-------------------------------------------------------
IN ---------------------------------------- OUT
-------------------------------------------------------
\ ---------------------------------------- /
-----------------------------------------
-----------------------------------------
```

If you could find (or make) 37.5 ohm coax, you would need only
two parallel coax lines instead of four. It would not be
necessary to use pairs of coax's to get 37.5 ohms per side for
a net 75 ohm balanced line.

Have fun!

For just 3 feet, he would be better off making the twinlead
himself out of copper or aluminum tubing. The diameter and spacing should
be easy to calculate or adjust from measurements.

In the olden days, that's the way *real* hams did everything.

Gary,

I would guess that the efficiency will be as good or better than a strip line or tuned line design. With the silver plating it will be a little better but not a whole lot. I would suggest using the 250. Use one of the 250 amp designs from an older ARRL handbook to determine the bias voltages required and how to key it on during transmit.

I would expect somewhere around 55 to 60 % effeciency. I have an AM-6154 amp that uses an 8930 which is essentially a 250 but with a larger plate diameter and around 350 watts dissapation. It works very well and I have gotten 350 or so watts out. I never bothered to calculate the efficiency. There is no reason why you shouldn't get 250 or so watts out.

The device that you're describing is presently being sold by a mil. surplus co. named Fair Radio, which is located in Lima Ohio. They may be able to supply you with some if not all of the schmatics of that unit. You can probably use a 4cx250 in it with no problems. One thing that you will to do is build a power supply for it,but if you look in any A.A.R.L. manuals, you be able to find a supply for vhf use using that tube. How you plan to use the amp also should be considered. Different modes require different voltages especially for ssb and fm. I hope this helps.

Your theory notwithstanding, 75 ohm twin lead HAS been available for decades. Look in any ARRL antenna handbook for 214-023. Transmitting type 75-ohm Twinlead has two stranded 7/21 conductors about equal to solid #12 wire with quite close spacing.

From: hduff@humnet.humberc.on.ca
Message-ID: <8224331276601@lss.humnet.humberc.on.ca>
Source record: 107847

I recently aquired a 16 channel Motorola MCX100 commercial VHF radio.
Wondering if anyone has any info on programming a PROM for it ?

This one has the "R2" VCO board...146 to 174 MHz.
I see by the schematic that it uses 6 nibbles (4 bits wide) for the
programming word. I also note that the PROM address is made up of
the channel selector inputs AND a few bits from the phase comparator/
PLL chip. It appears that the Addressing from the phase detector/PLL
gets clocked out and the data read back...6 times (for the 24 bit word).

I'm wondering how the data relates to the desired frequencies and
where the data should be placed (what addresses) ?
Also wondering what the synthesizer step size is ?

The easier solution to all this is to have someone program a PROM
for me but thats too easy :)

Curious....Hugh Duff VA3TO Toronto

>that green LEDs make excellent, high Q, varactors.

That's a great idea; I never even considered that possibility!! You wonder who thinks of this sort of thing, don't you? Has anybody done the same tests on the other colors?

Any good RF transistor has a good varactor in the reverse-biased collector-base junction. If you want a low-power varactor, pick a low power transistor. High power, use a power RF device.

I would like to make a simple oscillator to use with an HT on 2M to help some of my friends upgrade their licenses. What I was thinking about is whipping up a simple oscillator which could be hooked up to a telegraph key and then to the microphone connector on the HT.

How would I determine the maximum power output to the HT that would not blow out the microphone circuit. Also, could I power the device with a 9V battery and send the output from the oscillator into the mic input of the HT or would this cause any problems?

Thanks,

Golden E. Murray

: be greatly appreciated.

Try RF Parts Inc in San Marcos, CA. They advertize in most of the major amateur magazines. They may even have PIN switches and other supporting hardware modules that they don't advertize.

My 'hint' would be to interface to the brick(s) with a PC board and to be careful about getting good grounds; both in the contact between the brick itself and your heatsink and in the back side ground of the PC board you use. You should be able to transition directly to 50 ohm microstrip from the brick that way.

Also, be sure to bypass and decouple your supplies well. It may be possible with some bricks to destroy them with low frequency oscillations.

>From thom@newshost.li.net Tue Jan 23 18:01:07 MST 1996

>If you can can tell me which leads are the emmitter, collector and base
>I'd appreciate it...more importantly, if you could tell me how to figure
>it out, myself, I woun't have to bother you the next time.

If you take transistors two leads at a time, they look like two diodes
back to back, the O's being the leads coming out of the thing:

O---->|----O---|<-----O PNP

| pin1 | pin2 | pin3

O----|<----O--->|-----O NPN

The base is the center one IN THIS DIAGRAM, that is, the one that is
diode-connected to both other pins, but it NEED NOT BE the pin in the
center of the device. Usually the tab is the "emitter tab" if there is
one, but for the three-legs-in-a-row package, EBC and BCE are both common.

Neither applied polarity conducts through the outer pins IN THIS DIAGRAM,
up to the breakdown voltage of the device.

If you have a DMM with a diode test function (which tells you the forward
voltage drop of the junction when biased with some fixed, small current)
then you can identify the collector as the pin with a few mV less drop than
the emitter, with a few more mV drop.

The magnitude of the drop tells you what kind of transistor it is:
Simple silicon beasties have about 0.6 volt drop for both diodes (so
figures of, say, 0.592 volts base-collector, 0.595 volts base-emitter
might be typical values).

Darlingtons have twice the drop, so values near 1.2 volts (for silicon) are
seen between the pins.

Germanium (diodes, transistors) have only 0.1 to 0.3 volts drop, so you spot
those too, though another hint is that germanium has fallen by the wayside,
so the packages look old. The more modern packages, like the hemicylidrical
plastic TO-92, and all the RF-tab ceramic power things, were invented later,
and I know of no Ge transistors in these packages. For Ge too the BC diode
has a bit less forward drop than the BE diode.

I doubt Ge darlingtons are common enough to worry about.

JEFTS look like back-to-back diodes just like bipolars do, but differ in
having some moderate resistance between the "outer" (singly-connected) pins,
and this resistance changes markedly when you poke the "center"

(doubly-connected) pin. (Bipolars are open between E and C.) The former are D and S, the one you poke is the gate. I've heard contradictory claims that the D and S of JFETS are or are not interchangeable. Perhaps someone in the know could comment on this?

MOSFETS vary; one pin will be open both ways to the other two, this is the gate. Some FETS have protection diodes between S and D, so they look open or a resistor one way (depending on the potential of the gate at the moment) and look like a diode drop the other way, so you know which way the supply goes, but you won't know yet if it's p- or n- channel. If you keep the voltages low enough, like below a diode drop, I doubt you'd blow the thing hooking it up wrong in an attempt to learn which of the remaing pins is S and which is D (and by twiddling G, if it's p- or n-, and enhancement or depletion) - I think they look like low-value resistors one way, and I'm not sure what the other way, when the gate is biased towards conduction between the other two pins.

I've seen the BC junctions of 2N2222A's spec'd as high-performance diodes, not even using the third lead, and also as "superdiodes" made by tying B to C: these turn on much more quickly than diodes from the gain of the transistor (and so also the forward drop is a bit less than when looked at in the regular diode way). Many silicon E-B junctions look like shoddy 8V zeners, but using them this way might degrade the transistor if employed in the usual way later. Some of the earlier brown- or tan-plastic packaged transistors are unwittingly phototransistors, as the plastic is not perfectly opaque. Same with some early metal-can transistors, where the pins come out (and the light can come in) through brown plastic.

I hope this helps.

Hi Gary,

The other problem I think I will defintly run into is all of the RF
energy getting to the microprocessor. I'm not quite sure how to isolate
it, other than shielding the microprocessor in a metal enclosure.

This is not always true. 72 ohm transmitting line is a common
item and is readily available from a number of sources. Either
The Wireman, RF Connection, or Radio Works should have it.

The above equation applies only directly to air-insulated parallel conductors.
A non-air dielectric will lower the characteristic impedance, which is what you
see with 72 ohm transmitting line, which uses something like 14 or 12 gauge
wire close-spaced in solid dielectric.

Probably easier to take four sections of 300 ohm twinlead and connect
them in parallel. Just keep them safely separated.

>scale by interpolation on the measured points (or measure ALL the places
>where
>there are to be scale divisions!). I would suggest 10 or so measured
points.

I used to manage the D'Arsonval meter area of Prime Instruments. Our low quality "wigglers" had gross non-linearity over their measurement ranges, but the 90 degree deflection high quality movements were *very* linear.

As an interesting note, some customers specified their meters caliberated up to 100% high, but 0% low. That way the charging equipment they sold never "looked bad". That tolerance was necessary on 39 cent wholesale price meters!

Gross non-linearity was usually caused by non-linear spring pressure (the cheap meters either used magnetic zero return or a simple single turn spring), and the pole pieces being poorly constructed. The permanent magnet's poles did not surround the movable coil with a uniform air gap in the cheap meters, so flux density changed as the coil moved through it's arc.

Check the scale linearity when working with unknown meters, especially if the movements are cheaply made!

653. Announcing FilDes 2.0

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-25 00:00:00 UTC
From: blombard@iu.net
Message-ID: <4e6pmh$f96@cc.iu.net>
Source record: 107774

Announcing FilDes 2.0

I would like to draw your attention to the release of the newest
version of my popular filter design program, FilDes (also known as FDS).
FilDes 2.0 is major update to the previous version, and includes the
following new features:

* Design of Bessel (flat group delay) LP, HP and BP filters
* Design of Gaussian to -6 and Gaussian to -12 dB filters in
LP, HP and BP.
* Design of Linear Phase with 0.05 and 0.5 degree equiripple
phase error filters in LP, HP and BP.
* Extensive support built-in for ARRL Radio Designer (r) from
the ARRL and Compact Software(r).
* Computes duals of LP and HP filters for ease in diplexer
design or more realize-able component values.
* A filter "estimator" for Systems Engineers, and others who
don't want to build filters, but need to know how much filter
they need.
* Elimination of all-known bugs.

The following FilDes features are still there, or have been improved.

* Design of LP, HP, BP, BR and narrow BP filters in Butterworth
or Chebychev transfer functions with .001 to 3 dB of ripple.
* Design of Elliptic (Cauer) LP and HP filters.
* These designs carried out by synthesis, not look-up table.
* Calculation of the order required from these filter types to
meet your attenuation requirements.
* Output to text printer or Touchstone (r) .CKT file format.
* Estimate of midband insertion loss for BP filters, based on
component Q.
* Online, context-sensitive help.

The program comes with a companion utility called Airwndl (Air Wound L)
which calculates the number of turns for an air-wound single-layer
solenoid coil. A complete description of Fildes2 is included in the
file FilDes2.doc, and also as a Windows 3.1 Write (r) file, FilDes2.wri.
Everything is in a zipped archive called FDS200.ZIP. It is available
at ftp.lehigh.edu where it is currently found in /pub/listserv/qrp-l/tools.
I have also uploaded it to ftp.ee.ualberta.ca in the directory
/pub/cookbook/softw/ibm. It should be available there shortly.

73,
Bob

>>no one is yet shall we say an expert with it yet.

MFJ should have a cable for your radio to TNC
I use same one for my HTX-202 and IC-W21AT

The APRS experts have a SIG on TAPR.ORG called aprssig
(I am not an expert but I do have a set of notes on using the KPC-3 with
a GPS as a remote tracker)

set unprot to RELAY to get started then to a APRS digi station in your area.
Some of the setups for APRS (PC) or MACAPRS will do this for you.

Hi all,

as I tend to use my Usenet browser quite unregulary, I'd prefer to retrieve the traffic of the last few months or so at an archive site. I know the official archive site of r.r.a.antenna and of r.r.a.homebrew somewhere at a stateside location, but the slowness of my access takes the fun out of it.

I'd like to know an archive site for the rec.radio.amateur.* newsgroups somewhere in Europe. I don't need an FTP site for programms or stuff, just archived Usenet traffic. Do you know any, over here in the Old World?

Vy 73,
Richard

Here is a circuit that we used at the local PRBBS for auto-QSY when we had an FT-747GX. Be warned: it is *crude*. It doesn't 'listen' to the radio and it has no provision to avoid sending a command if the radio is not 'ready'. OTOH it worked, I was able to build it into the DB25 computer connector, and it was dirt cheap. If your application is something like auto-QSY of a BBS for forwarding, give it a try. If you need a full-service CAT function, better stick with the FIF-232C or equivalent:

```
47 j
10 Kj |/ -----/\/\/\----- -------> FT-747GX
>----/\/\/\------ --- ------| Si NPN | CAT input
DB25-2 | | |\>-- ___ (+5v/680j)
TXD ___ ___ | .01 ufd ___
Si ^ ___ .01 ufd ___ |
| | /// |
| | ___
___ ___ ///
/// ///
```

The diode and transistor can be whatever you have in your junk box - not critical.

Hope this helps - have fun and 73 -

Paul Egan (ai657@freenet.toronto.on.ca) wrote:

: I need some help repairing an Eddystone EC-10 SW rig.
: I have the manual and have tested the transistors using the
: figures in the "Voltage Analysis" section.
: All seemed close to the values quoted except TR4 & TR5 (IF Amp).
: TR4 should be 0.87v (E) 1.15(B) 5.6(C) but is 0.36(E) .64(B) 1.71(C)
: TR5 should be 0.40v (E) 0.70(B) 7.5(C) but is 0.05(E) .28(B) 0.28(C)

Without a manual in front of a reader, this won't help much.

I've fixed several EC10's though the last was some years ago. They're twee enough to want to fix, but not particularly good performers, though.

What I found were loads of dead transistors. I suspect most of the OC170 OC171 devices have an age related silent failure mechanism. The AF115 or was it AF117 was notorious.

A bit of artful recalculation of bias resistors and fitment of some fairly docile modern silicon devices ought to be possible.

Reliability of resistors and larger values of capacitors of that period was a bit poor, too. A rebuild may make more sense than a repair.

Cheers
David

666. McGreevy BBB-4 VLF/ELF -whistler- receiver schematic

The "BBB-4" is a broadband 0.2 to 11 kHz V.L.F. receiver with a passband peak at approximately 2 kHz, and is designed to receive naturally-occurring V.L.F. phenomena (such as "whistlers") that occur as electromagnetic (radio) waves at audio-frequencies. This receiver was designed to be hand-held, and its output patched to a microphone-level input such as a tape-recorder or speaker-amplifier (such as the one available at Radio Shack ("Mini Audio Amplifier/Speaker" cat. # 277-1008).

Dissatisfied with more complicated and cumbersome multi-turn loop receiver schemes, I opted to design a whistler receiver which was simple to build and use, but was as sensitive and low-noise as possible while being highly-immune to broadcast station overload.

The BBB-4 V.L.F. receiver circuit ("BBB-4" standing for a fourth version of my "Bare-Bones-Basic" designs) is remarkably sensitive and works very well with short whip antennas between 30-60 inches in length, since it operates on the same principle as high-impedance "active antennas" designed for other frequency ranges (such as long, medium or shortwaves). The BBB-4, due to its F.E.T. "front-end" being a high-performance J-FET, has an input impedance of about 10 megohms, which is why the short whip antenna--more correctly called an "electrical-field probe"--works fantastically for being such a tiny fraction of the received-frequencies' wavelengths in size (the ultimate isotropic antenna).

R1 and C2 act as a roll-off to frequencies above about 20 kHz, efficiently eliminating potential receiver overload/intermod from Loran-C (100 kHz), strong AM-BCB signals or SWBC signals, and frequencies up into the VHF ranges. R2 sets the gate impedance for the J-FET. R4 and R3 set the optimum bias on the FET for maximum dynamic range and minimum

susceptibility to overload and intermod. C3 and C6 slightly helps roll-off low-frequencies such as powerline "hum." The "pi-filter" consisting of C4, L1 and C5 roll-off frequencies beginning at about 7 kHz, so there are not excessive levels of 10.2 - 13.6 kHz "Omega" signals or higher frequency signals, which can create problems with the recording system connected to the output of the receiver. R5 to R8 , Q2 and C7 form a fairly low-noise Class-A audio amplifier which boosts the output from Q1 to a level plenty for all microphone-level recorder inputs and even some more "sensitive" line-level inputs. Bypassing R3 (1K) with a 2.2 uF cap will boost FET gain somewhat, esp. the higher frequencies--depending on your location and listening conditions, this may or may not be desireable.

The circuit can be built on perfboard such as IC-LSI boards or even wired point-to-point, as layout is not very critical. However, the parts' values ARE critical for optimum passband shape and sensitivity. L1, the inductor, can either be a 160-200 mH choke or the Radio-Shack 1K to 8 ohm audio transformer available at Radio-Shack (cat. # 273-1380). Use the black and green or black and blue wires (the center-tap and one end of the primary winding). The audio transformer was used since it is easily available at Radio Shack stores. In fact, ALL the parts with the exception of the 2N5484 FET are available at Radio Shack. Very good performance (but slightly reduced gain) can also be had if a 2N3819 J-FET, available at Radio Shack, is used. If so, R3 must be 220 ohm and R4 must be 1K, because the 2N3819 needs different biasing than the 2N5484. Also, if you use the Radio Shack 2N3819 FET, you might wish to reduce C4 and C5 to .0033 mF, since there will be less high audio-frequency output from the 2N3819. Keep C4 and C5 0047 mF if you live within a few hundred miles/km any Omega Navigation Station (Omega transmitters frequency-step from 10.2 to 13.6 kHz) .

Capacitors C4 and C5 work with L1 to reduce Omega to tolerable levels.

Solder the J-FET into the circuit LAST, and take measures to protect the FET from static electricity.

The total cost for parts (not including an enclosure) for the BBB-4 are in the neighborhood of $15-20 U.S. A rugged telescoping-whip antenna is the GROVE ENTERPRISES "ANT-8" 7-46-inch telescoping whip with a BNC connector. This is available for $16.95 from Grove Enterprises, P.O. Box 98, Brasstown, NC 28902-0098, U.S.A. (Order Line 1 (800) 438-8155. They send out a free catalog.

Another telescoping whip antenna of like design is available from C. CRANE RADIO CO. in Fortuna, CA in Fortuna, California (800) 522-TUNE (522-8863). E-field-probe receivers of this type need to be operated at locations away from trees, buildings, or other obstacles by about 100 feet/30 meters. This is because received signal levels (due to E-field attenuation) will be poor if the receiver is operated too near (or under) such obstructions.

The greatest nemesis to monitoring and recording naturally occurring VLF phenomena are electric a.c. powerlines, which emit annoying hum at 50/60 Hertz and also harmonics beyond 3 kHz. The only cure for this "hum"

problem it to locate monitoring sites well away from a.c. powerlines. Locations at least 1/2 mile/1 km or so away from a.c. powerlines will begin to be acceptable, though the farther you can get from powerlines, the better.

Hilly or mountainous terrain (with open areas free of trees) offer larger areas away from powerlines, though large fields and meadows where the powerlines are shielded by trees, etc. may be surprisingly hum-free. Remote locations such as deep into desert and wilderness regions offer the most rewarding locations, both aesthetically and electrically, to listen, and you may be able to get over 10 miles from the nearest powerline. If so, you can make the receiver's antenna several meters in length (keeping it vertical) for maximum sensitivity. Longer vertical antennas or horizontal wires may either overload the receiver, or in the case of long/low wires, will create a mismatch which will actually reduce output. Experiment here.

NOTE: A 100 mH choke across C5 (th secone .47 cap in the audio filter will greatly reduce the below 1 kHz frequencies, including pesky power-line hum. This may enable you to listen far closer to AC power-lines including even some backyard locations!

Grounding is non-critical. High-impedance FET receivers of this type need only minimal grounding to work well_even just the body of the listener holding the metal enclosure of the receiver will be adequate in most cases. If recording, it is best to stick a 8-10 inch ground rod into the soil to reduce the possibility of feedback with some tape recorders. Also, a small ground-rod (8-10 inches long) will cut noise from body or foot movements (due to capacitive interaction with the ground). If you ground the receiver to objects such as fences, beware that certain grounds may couple a.c. powerline noise to the receiver, which is why I recommend a simple Earth ground.

Better quality tape recorders, with adjustable input level controls, are desirable, as "cheapie" portable recorders with auto-level control will often have annoying variations in record level due to lightning-sferics. And, these cheap recorders also put noise of their own onto the tape. A shielded 600 ohm patch-cord will suffice between the output of the BBB-4 and microphone input of a tape recorder.

The most common naturally occurring V.L.F. emissions to be heard are the myriad "crackling and popping" sounds of lightning-stroke electromagnetic impulses from lightning storms within a couple thousand-mile radius of the listener. Since there are nearly 100 lightning storms in progress anywhere on the Earth at any given time, and that millions of lightning strokes happen daily, there is never a moment when these lightning "sferics" will not be heard. However, the density and strength of lightning sferics can vary day-to-day and hour-to-hour. Mid-winter offers the lowest density of sferics, and summer evenings can be full of a dense barrage of strong sferics.

The other most common (and most awesome) sounds are "whistlers"_eerie descending tones caused when the lightning electromagnetic energy gets "ducted" along Earth's magnetic lines-of-force (magnetosphere) to the opposite polar hemisphere, then gets rebounded back to the vicinity of the

originating lightning stroke impulse. However, there doesn't have to be lightning within sight or even a few hundred miles of your listening location_lightning from storms up to thousands of miles away, particularly if more to the north of your location, can generate large whistlers which are heard continent-wide. On the other hand, it's quite spectacular to watch distant lightning storms generate whistlers in the receiver's output_you hear the huge "crack" of the lightning impulse sferic, then, if the conditions to support whistlers are occurring, a whistler may follow from 1 to 2 seconds after the lightning stroke.

Optimum times to listen for natural V.L.F. phenomena, such as whistlers, are between sunset and sunrise, with the midnight to sunrise period generally being the best. Statistically, the greatest activity to be heard is around dawn and sunrise (4-7 a.m. local time)_sferics tend to be fairly low as compared to the sunset period.

Dawn Chorus can occur during magnetic-storms, and will peak anywhere from an hour before sunrise to 2 hours past sunrise. Whistlers can occur at anytime, but the period of minimum frequency is midday. Sometimes, activity can also occur just after sunset, but sferics will be fiercer. Lightning sferics will be most fierce during summer afternoons and minimum (generally) an hour or so after sunrise until thunderstorm activity picks up later on. Winter can present delightfully low lightning sferics_other activity will be more "in the clear."

Tweeks, the "ringing/pinging" sounds of sferics caused by the Earth-surface/ionosphere "waveguide," will be best from an hour after sunset to 2-3 a.m. local time, gradually tapering off toward sunrise. Their number and intensity of "pinginess" can vary from night to night_some nights they can sound rather "pale," but other nights they can ring in a variety of beautiful mixtures and pitches. Whistlers, which may or may not be heard on some days or even weeks, can range in sound from quite pure notes to very diffuse "breathy" sounds. They can swoop in frequency from very high to low, or abruptly cut-off as they descend in pitch.

Don't be discouraged if you listen for several hours, or several sessions on different days, without hearing whistlers or other natural radio phenomena. When you DO hear them, it will make up for the "dry" times, as there is nothing like "live" listening!

Listeners located north between 40-55 degrees north or south latitude are in the optimum latitudes for monitoring natural V.L.F. phenomena. If you can see visible Aurora (Northern/Southern Lights) from your location, you are at a great location for natural V.L.F phenomena monitoring! Latitudes between 20-30 degrees north and south will hear less, but at times, still loud phenomena. I've heard whistlers just fine in Hawaii_presumably those whistlers were louder farther north, but still, they were heard!

DO NOT operate this receiver (or any other) when nearby lightning threatens! Take appropriate lightning precautions when lightning is occurring nearby (within 5-10 miles). Nearby lightning will cause excessively loud sferics in the receiver's output, and whistlers will not be

louder just because lightning is close-by. Reserve listening for fair weather periods_most often, the best and loudest natural V.L.F. phenomena will happen during clear weather, since lightning can be quite distant, as mentioned above, and still spawn loud whistlers.

If you would like to purchase a ready-made receiver which is fashioned like a "Walkman-style" whistler receiver, e-mail me for details. I don't want to "advertise" here.

The Longwave Club of America also has other designs of ELF/VLF "whistler" receivers, and has a BBS run by member John Davis. The LWCA BBS is at (706) 672-0360 with speeds up to 9600 (8,N,1). Download the ALLFILES.TXT or ALLFILES.ZIP for listing of files avail on this BBS.

A WWW URL of natural radio WAV files (most 8 bit/11 kHz sampling compatible with Windows "speaker.drv" as well as 8-bit sound cards, plus a few 16-bit files for 16-bit sound cards are available for downloading at:

http://www-pw.physics.uiowa.edu/mcgreevy/

Special thanks to Larry Granroth a the U. of Iowa for doing this for me!

Coordinated monitoring of naturally occurring V.L.F. phenomena among individuals and groups has a strong potential to uncover new and previously unknown characteristics of these phenomena, particularly if those monitoring simultaneously are located hundreds and thousands of miles apart. Research and understanding of V.L.F. phenomena has been hindered by a lack of listeners, which is something a few research groups, both amateur and professional, are attempting to alleviate.

I hope you enjoy this receiver and are interested in monitoring and studying naturally occurring VLF radio phenomena for yourself. It is quite fascinating, especially when one ponders the fact that Earth's natural radio emissions have been "sounding-off" way before we Humans came into existence and started making radio waves of our own! Happy Listening!

Stephen P. McGreevy
Originally released November 1993, updated November 1995, January 1996 with thanks to many rec.radio.shortwave readers!!!

Additional Tips:

1) A 100-200 mH inductor connected across C5 the will act as a high-pass filter, nicely attenuating 60-360 Hz powerline emissions (hum).

2) If you want less gain from the Q2 stage (and slightly lower noise), reduce R8
to 4.7K.

3) Listen to WWV-shortwave (2.5, 5, 10, 15, 20 MHz) for geo-magnetic indices at 18 min. past each hour (WWVH-Hawaii at :45). A K-index at or above 3 indicates enhanced conditions for natural phenomena,
especially chorus.

4) the U.S. NOAA/USAF runs a fantastic Gopher URL with geomagnetic indices
and other information available at:

gopher://proton.sel.noaa.gov:70/11/forecasts/SGAS

Lists the past 30+ days' geomagnetic conditions, proton and electron fluences,
and so forth.

There is a rough correlation between high electron fluences and whistlers--
look for fluences at 1.0E + 07 or higher. Periods when the solar fulx is
rising also seem to be times when whistlers occur more often.

If you type in the URL without the "SGAS," you will get to the main menu.

73,

Stephen P. McGreevy, N6NKS

I think there is not. Filaments (heaters) can be checked with an ohm-
meter (and possible shorts between electrodes).
Were the tubes in their carton boxes or loose?
Tubes without boxes are probably used - some of them can be good still.
A tube tester would tell something, but it is hard to find one nowadays.
(And even harder to find a person who knows how to use it.)

>
>Warren EI6ETB

Why mess with varactors? They're a pain in the tush. Hard to get them working, and prone to weird oscillations. Build a bipolar tripler; lots of good devices at 1 GHz. Also, even better to start lower in frequency, if possible, and use two doublers.

These are pretty common old tubes. Many are used in the classical "All American five" five-tube radio chassis. They're available from a few sources these days, mostly made in Easter Europe. Not worth squat. Sorry.

Message-ID: <4e8l94$ib3@maureen.teleport.com>
Source record: 107797

; dmiller@crl.com (Donald J. Miller) writes:
; Gary Stone (garystone@texoma.com) wrote:

; : My brother-n-law (KI7XQ) is looking for about 3 feet of 72 ohm twinlead
; : for a balun on an antenna project. I know very little of the project,
; : but he does not have internet and I wanted to try and locate a source for
; : him.

; You can't realize this transmission line with twinlead construction.
; For an impedance that low, the diameter of the conductors is greater
; than the spacing:

; s = center to center spacing
; d = wire diameter

; Zo = 276 LOG(2s/d)

The formula you quote is an approximation, which falls apart with close spacing/large conductors, as you found. The correct formula is

Zo = 120 cosh^-1 (s/d)

where cosh^-1 is arc hyperbolic cosine.

This is for air dielectric. The presence of other material between the conductors will lower the impedance.

72 ohm twinlead used to be common stuff, in two sizes, "receiving" and "transmitting". I've got a bit of the transmitting stuff in my junk box, but it's too large and stiff for practical use in a balun. In this day and age, I'd use twisted pair with thinnish insulation. Unless it's being used at a frequency where 3 feet is an appreciable fraction of a wavelength, the Zo of the line probably won't be very important.

> > Is there a simple way to tell if the tubes are good ?

Not really but the two tests below will find most bad tubes. It will not pick up weak tubes but even then a repair shop replaced tubes, perhaps 20 % of the tubes they replaced were actually bad (I know because the local TV repair shop's trash can was a favorite hangout on trash day and nearly all the tubes I scrounged tested good on a real tube tester!)

1. Use an ohmmeter to test for filament continuity. The nice thing about tubes (aside from their cheery glow) is that you can see inside - you can locate the filametn by tracing from the pins - it will be the whitish fine wire in the center of each of the sections. Or, it is almost always pins 3,4 on a 7 pin tube and 4,5 on a 9 pin tube.

2. Look for a silvery metal spot inside the tube. If you see this, the vacuum is intact. If it is milky white or red, the tube has lost its vacuum.

These are all very common tube types. Even today, they sell for less than $10 new. Years ago they were around $1-2.

The mentioned "thin" traces on the board are for logic control and
not RF (a typical width for digital circuitry). The RF lines, you will
note are much thicker.
My concern was that a groundplane was not utilized, instead...the
unused copper was etched away. I would have kept the copper on any
unused areas on either side of the board with lots of plated thru holes
to help shield the digital control lines from the RF.

I suspect that most of them are ferrite cores for noise suppression
use however there are several bins at the surplus store with
wound cores that look more like RF transformers.
Nevertheless, I get the feeling that it is not worth the effort
to try and salvage a small assortment of RF capable iron cores.
Just a passing thought though !

>good as mine. But this is progress :-)

Personally, I think the obsession with removing rosin flux is cosmetic. My
only measurement experience with this is from over 15 years ago when I was still
a technician. Used to work for a place that made very precise measurement
equipment for computer control of all sorts of industrial stuff (everything
from making chocolate at Hershey's to reclaiming silver at Kodak). The most
sophisticated amplifier card we had, with a gain of 2048 in a system that read
down to microvolts per bit, was sensitive to contamination. Skin oils would
drive readings off, invalidate input bias current measurements, and other things.
Rosin flux was essentially inert. I saw cards come back from the field with
flux on them for years and it was never a problem.

I would guess that an activated flux might be a problem, but I've never seen
studies on it, or had experience with it.

Hi
I'm trying to obtain a VCO covering 1 - 2 gHz for use in a
spectrum analyser project. I know Minicircuits (USA)
manufacture a range of VCO modules but I am told that they
are un-available in Australia due to future production being
sold out.

If you know of an outlet for these units, or any other
types, or have a proven circuit, please let me know.

Many thanks in advance... Steve

692. WTB: Old mechanical calculators

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-26 00:00:00 UTC
From: phil@SANDH.COM
Message-ID: <0000265000000A7D@SANDH.COM>
Source record: 107725

I am interested in purchasing old mechanical calculators and slide rules.

I collect the old electro-mechanical "rotary" calculators that were made by Friden, Marchant, Monroe, and other manufacturers from the period of the 1900's through the late 1960's. I also collect non-electrical mechanical calculators and am especially interested in hand-held Curta brand calculators. I am not interested in adding machines that print on tape or electronic calculators.

If you have an old mechanical calculator or slide rule collecting dust in a closet, please send me an e-mail message.

|vacuum tubes:
|
| Magnavox 12BA6
| Magnavox 12BE6
| Magnavox 12AV6
| RCA Electron Tube 35C5
| Sentinel 12BE6
| TEN 12BE6
| General Electric MA?
| ?? 12BA6
| ?? 12AV6
| ?? 35 W4 (2)
|
|Is there a simple way to tell if the tubes are good ? How
|would I find out if they have any value ? How would one go about
|or, more likely, donating them ?
```

Hah, you probably have some tubes from those AC/DC line transformerless radios. The 35C5 is a power pentode or tetrode. The 35W4 is a rectifier. The 12BE6 is a converter. The 12AV6 is a dual triode. If I remember correctly the filament current is 0.15A. They were usually wired in series to make up 100-120V worth of voltage drop which is just right for US power standard.

Just give them to a tube enthusiast. He/she will know what to do with them.

Bothers me that I actually can remember this stuff. :-)

I doubt they're sold out, but my catalog shows their highest frequency model to be the POS-1025 which tunes from ~615 to 1050 MHz.

>If you know of an outlet for these units, or any other
>types, or have a proven circuit, please let me know.

There are other USA vendors, such as HP/Avantek and VariL, however, if you only want one or two pieces, forget them.

From: David Negaard <draagen@connectnet.com>
Message-ID: <3109B56E.3A080BB4@connectnet.com>
Source record: 107732

I'm looking for plans for a simple (probably crystal-controlled)
transceiver that would be suitable for 9600 bps packet use. Does anyone
know where I might obtain same?

My hand-held won't cut it, of course (PM instead of true FM), and I
can't really afford to buy another radio right now.

Also, I assume that a radio suitable for 9600 bps would also function
admirably at 1200?

700. Printer Port Manual

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-26 00:00:00 UTC
From: "Peter H. Anderson" <pha@access1.digex.net>
Message-ID: <Pine.SUN.3.91.960126130009.9634A-100000@access1.digex.net>
Source record: 107733

I recently completed a manual on how to use the printer port. It is intended for electrical engineering students who have completed introductory courses in circuit analysis, digital and C programming.

Peter H. Anderson, "Use of a PC Printer Port for Control and Data Acquisition", 106 pages, Jan, 96. - $7.00 including postage.

Copies may be ordered by sending a check or money order made payable to "IEEE" to;

Peter H. Anderson
Dept of Electrical Engineering
Morgan State University
Baltimore, MD 21239

The manual illustrates how to use the printer port on any PC Clone to control motors, electro- mechanical relays, stepping motors and to acquire data using both an analog to digital converter and by measuring time.

Topics include; printer port layout and programming techniques, how to interface with a breadboard, use of a junk PC power supply to power peripheral circuits, driver circuits, Darlington transistor drivers, optoisolators, grounding considerations, expanding the input and output capability, inte rfacing with 7-seg LEDs, controlling the speed of a DC motor, infrared remote control, radio frequency remote control, digital to analog conversion, analog to digital conversion, acquisition of temperature data using a thermistor, forcing an interrupt, use of an interrupt to measure temperature by measuring time, use of an interrupt to determine the gravitational constant g.

In the future, this will be expanded to include such topics as range finding using sonar, interfacing with a LCD panel, speech synthesis, use of digital and linear Hall effect devices, fluid level detection, pressure transducers and the design of sensor conditioning circuitry.

0.2dB is commonly used in EME and other path loss budgets for a balun made of low-loss cable.

As well as dissipative losses in the half-wavelength of cable, this figure is usually taken to include losses due to phase errors and radiation losses in connecting to the folded dipole. In other words it is not directly measurable by methods such as connecting two identical baluns back-to-back.

I guess it's really just a "wet-finger" allowance that people make when converting from computed gain to real-world gain.

From: hduff@humnet.humberc.on.ca
Message-ID: <8227073035401@lss.humnet.humberc.on.ca>
Source record: 107736

I've been thinking about my radio equipment in the car...
I wonder if there is any data to suggest that long term temperature cycling ie.. -20 degs. C to about +20 degs. C that occurs in the Northern climates can have detrimental effects on the lifespan of electronic components, especially electrolytic capacitors, LCD displays and any other components with liquids in them ???
With the car sitting all night in sub freezing temperatures, then the heater warming the cab of a car up to a comfortable level during the drive to work...I wonder if this stresses the electronic components ? (I'm sure it must !?!?)
I know that manufacturers do temperature cycling tests in environmental chambers on their products to be able to spec the operating and sometimes the storage temperature ranges but I'm curious to know if any longterm testing is conclusive on the MTBF of electronic products ?

I'm not doing a study...just a curious mind !

Source record: 107737

Hi:
A company called Mitsubishi Material makes an awesome surge protector.
It's fast and once it's clamping voltage is exceede it's holding
voltage drops to nearly zero. This may provide better protection than a MOV
for a radio's input and also for phone lines, and modems. The device incidentally
has less than 1 pF of capacitance so it's easier to use than a MOV. It can take
repeated hits and it's characteristics stay constant were as MOV can deteriorate.

Don't have a source for those, but here's a thought for you.

A guy who is more clever than I am decided that all diodes have those properties, and the only difference was that varactors were specially doped to emphasize them. So he made a "varactor" tripler out of some 1N914 diodes. Worked fine, but I think he said they were a little lossier.

That was about 12 or 15 years ago, and I think it was even a commercial product, so it was repeatable.

The guy was WA4GHK.

Source record: 107812

WD-40 is great stuff. I used to work building bridges and several times my walkie talkie (ham) fell into the salt water. My standard procedure was to leave it where it fell, remembering where it was. I would go back after work with SCUBA, retrieve the radio and put it into a bucket of water from the bay. Then upon returning home, I would dip the radio into alcohol and blow it out with air pressure. I did that several times until I was sure all the water I could get to was displaced. Then, I would spray it full of WD-40 and blow it out again, doing this at least two times to get the WD-40 into all the crevices. I never damaged a radio and did this at least 4 times with one unit. Only the battery wire from the terminal to the battery would burn out while it was under water. I would take the radio to work the next day.

MARKET MANAGER - ANTENNA PRODUCTS

Larsen Electronics is an internationally recognized supplier of quality antenna products for two-way communications. We are seeking an experienced Market/Product Manager for Amateur and Commercial antennas.

Successful candidates will have in-depth experience in radio related products up to 800 MHz. Direct experience with LMR and Amateur markets is preferred. Bachelor92s degree in Business or Marketing, or extensive related business experience required. Position responsibilities include: Product line management, pricing, sales programs, new products, training, and technical support. This position will also include a competitive compensation, incentive, and benefits plan.

Interested candidates may respond by forwarding a resume92 including income history to:

Larsen Electronics, Inc.
ATT: Human Resources Manager
P.O. Box 1799
Vancouver, WA. 98668-1799
FAX: 1-360-944-7556

Pre-employment drug screen required. Larsen Electronics is an Equal Opportunity Employer.

714. Kit HF receivers

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-26 00:00:00 UTC
From: davide70@aol.com
Message-ID: <4eb81n$a7l@newsbf02.news.aol.com>
Source record: 107818

Do any manufacturers still make "low-tech" SW receivers or kits? I've seen one that MFJ sells (a regenerative set) -- does anyone know if it actually works? It claims CW and SSB as well as AM. Should I believe that? If it performs up to its claims it would be perfect for my purposes. Any suggestions for me? Thanks.

Dave Ek

715. Re: dummy load?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-26 00:00:00 UTC
From: rst-engr@oro.net
Message-ID: <4ebd96$hpg@hg.oro.net>

>Could someone either send me,or direct me to a site where I might find plans
>to construct an inexpensive dummy load (50 ohm).I don't need it to handle
>more than 10 to 15 watts maximum.Thanx!

Sure, how about a 10 watt load. You can probably figure out a way to make it a 15 watt load if you want to later increase the power once you understand the basics. All it takes is 15 resistors instead of 10 and a change in resistor value.

And how about we go into it using a BNC connector?

Get yourself a piece of scrap single or double-sided PC board material 2" square or so (or a piece of copper plumbing flashing sheet the same size), a UG-1094 BNC female connector, and ten 510 ohm, 1 watt carbon film resistors. (Sources at the end of this post.)

(Alright, for you 50-ohm purists. Eight 510 ohm and two 470 ohm resistors. I'm trying to keep this simple and cheap for the kid.)

Drill a 3/8" hole in the dead center of the PC board and mount the connector with the center solder cup pin on the copper side of the board. Be sure the lockwasher on the connector makes good contact with the copper foil.

Using the minimum possible lead-length connect one end of each of those resistors to the center pin of the connector (it is going to be a big glob of resistor leads, but make it as neat as you can) and the other end of those resistors to the copper foil. The trick is to arrange the resistors like the spokes of a wheel so that the net effect is all the resistors coming off the center pin and going to their own little patch of copper foil with equal spacing on all the resistors.

It is very important to (a) keep the lead length on the resistors as short as possible, certainly below 1 cm (1/2") and (b) keep the center part of the body of the resistor AWAY from the foil to the extent possible. I'll try an ascii drawing:

```
__ solder resistors to center pin
resistor /[__]----|__ of connector here
------------/-------[ ]--------------------Copper ground plane--
solder to [ ] BNC Connector
top of board
here
```

(My ASCII art isn't quite as well developed as my RF stuff yet.)

Source: Copper PC board scraps at any electronic "junk" store or Radio Snack. Connector and resistors at Mouser Electronics -- call 1-800-346-6873 for their latest catalog. Connector is $2 or so, and resistors are a nickel apiece in hundreds or a dime apiece in onesie-twosies. Whole thing shouldn't cost you $5.

>may or may not be any good!). Is this the way it is in your area of the
>world? What would make a piece of HB gear more valuable to the astute
>buyer?

Hi John....the very best way for homebrew gear to attain
value, is 1. quality construction, 2. quality outward
appearance, 3. documentation, 4. good salesmanship.

As far as the average ham not being competent to
build...that can be debated. Many hams are all thumbs, many
are competent kit builders, lots are great from scratch but
the final product looks awful (works great though). Then
there is that few that can take a box of junk, build the
best looking, functional and loaded with bells and whistles
piece of equipment. So if you want a good piece of homebrew
equipment, learn the principles behind the box, and either
build it yourself or look deep into the construction of your
potential purchase.

Well unless my eyes have failed me, my December QEX just arrived complete with a feature article on a mpu based receiver controller that is cute and usable, but like the antenna tuner article this article does not offer any vehicle to obtain source code--but the author's company is willing to sell a kit; a kit which looks to be reasonably price, but a commercial product none the less. This again brings up the question of article vs. review. Perhaps a few letters to our elected Division Directors would bring this to the attention of League officials--

I've got a 148gtl working now on 10. I spent quite a bit of time scanning the 'rec.radio.cb' and finally got the 'best of the best' from all the info on converting it. I also happen to know a part time tech for a local CB shop. We actually did the conversion 'over the air' - he read me the instrutions and I made changes.

The simplest method for putting it up on ten was just to change the crystal according to this formula:

I actually found an '11.7830' crystal in the misc. crystal
bin at a local surplus electronics store - it covers from
28.345 to 28.0.

The mod for the 'clarifier' depends on the vintage of the
148gtl. Apparently there are two mods, one for the old style
radio and one for the new. I can supply the one for the new one
if anyone is interested. Mine tunes about +-10khz.

I guess I should just put everything together and post it all.
My next mod is going to be the one with the PLL so it will
tune 29mhz - and then a crystal calibrator and an FM mod.

Not a bad radio for a winter project! (and only cost 50 bucks)

You think that's bad, look at the Feb 96 QST. There's a "feature"
article that's nothing but an advertisement for the 96 Handbook.
And one of the columns answers reader questions with instructions
for ordering this League publication or that League publication
rather than just giving a straight forward answer to the question.
It appears that the feature and columnist pages of "the catalog"
have now been co-opted to advertise League wares as well as the
color ad section in the back.

I don't know about you, but I find this distressing. I expect
ads in QST, I expect ads for ARRL products in QST, but I don't
expect the editorial content to be turned into nothing more than
advertisements. I think it has become time to take a hard look
at ARRL publication editorial policy.

Someone just gave me, the local certified "junk collector", a dozen
A59RX tubes in boxes, plus a couple of loose ones. I can't find it
in any of my many manuals. It LOOKS like some kind of photodetector,
with a half-cylinder "reflector", but, instead of running down the
axis, the "collector" wire is a square loop kinda runing around the
edge of the half-cylinder.

Can anyone tell me what it really is. I won't add it to the clutter if
it doesn't have some potential use greater than a one-time rifle target.

Ken,

While I use the toner transfer method to make quick boards I still fall back to the photographic method for more complicated boards or those that I want to be near perfect. I have not found a way to get a good transfer from a paper source. I have been able to do it with photographic methods.

GC Electronics had a film (I guess they still do) that could be used to lift an image from a printed source to create a negative. It is an interesting process that they used. They put the film on top of the paper immage. They used the reflectivity of the paper, white vs the black traces, to expose the film. The reflection caused more exposure over the white areas than the black traces. You could create a positive or a negative. One required a second sheet of film to reverse the image. This is more work than using a transparency for the original artwork. I don't use this method unless I a using artwork from a magazine.

Most of the time I create my own artwork and print it on transparency using my Laerjet 4+ printer. I then purchase presensitized (positive type) PC boards from PCB Kits. I gave up on "spray your own resist" since I never could get the stuff to stick or be consistant in thickness. Lay the transparency over the presensitized board between a piece of glass. Expose with a photoflood light. Develope the board in a developer from PCB Kits. Let dry and then dump in the etch tank. It is actually easy to do and does not take much more time than the toner transfer method. You don't need a darkroom or any special equipment. I use a 40watt light bulb in my utility room when working with the sensitized board. The only "photograph" equipment I bought was the photoflood.

A 3x6 single sided epoxy-glass board runs around $3.33, double sided is $3.81. These are year old prices so they may have changed slightly. Developer was $4.95/quart the last time I bought some. Standard board sizes range from 4x4 inches to 12x12.

I never see this company advertise in any ham magazines. I ran across them at the Dayton Hamvention several years ago. I called them last week so I know they are still in business. Give them a call and request information if you

want to try the photography method.

There are two sides to this.

On the one hand, it's bad policy to hijack magazine space allocated to feature articles in order to plug a new publication (regardless of who publishes it).

On the other hand, I find in my monthly question-and-answer column that many of the questions can be answered straight out of existing major handbooks. In such cases it's a waste of space to repeat standard information unless there's something extra to be added.

The other problem is that it isn't always possible to give a full explanation in the space available, so once again it's necessary to recommend a book. Sometimes this may look like a plug, but it isn't. For example, for further reading on any aspect of VHF/UHF DX, I almost always recommend my own book - not from vanity or for gain, but because it contains everything that I and several others knew about the subject when we wrote it!

You'd imagine that every ham in the USA would own a copy of the ARRL Handbook and would know roughly where to find information in it. But the inquiries to this newsgroup (and no doubt to ARRL) show that ain't so. The culture seems to have changed, and many radio hams just don't seem to buy books any more, or know how to find things out from them.

That's why I keep on telling people: Buy books and read them, because most of what you want to know is already in there. Or if you want it in netspeak, think of the ARRL Handbook as amateur radio's FAQ file.

I use WD-40 all the time on swiches (rotary, AC power, relays, you name it), noisy potentiometers, sticky slugs in old UHF rig inductors, locks, and anything else that slides or turns. Doesn't hurt any of 'em. It's one of the Great Inventions of the 20th Century (along with latex paint and plastic drinking straws. .)

V>I have a 3 cavity mobile VHF duplexer that I would like to re-configure
>as a 2m bandpass filter. Is this possible? How would I go about it?

Hi John:

You have made curious. I wonder what a 3 cavity mobile duplexer
is used for?

If the cavities are full size band pass/ band reject type
you could possibly utilized one ~as is~ for a front end band pass filter
but it probably will limit your operational band coverage on 2 meters.
You would also need to make sure the band reject notch is tuned well
away from the band segment of interest.

BTW Sinclabs had a 2 meter two cavity bandpass filter designed
for mobile operation available a couple of years ago.

WD-40 is a good water displacer (that's what the WD stands for),
it's a fair penetrating oil, and a poor lubricant. It can leave
a sticky residue which can accumulate and hold dirt. There are
better products for each of its uses, though few are as universal.

A better way to deal with electronic equipment dunked in salt
water is to soak it in a warm fresh water bubble bath solution
for an hour or two. Then rinse is throughly with clean warm
water. This will remove the salt residue much more completely
than using alcohol or WD-40, neither of which are solvents for
salt. You can then blow out as much water as possible and let
it air dry in a warm dry place overnight. This is what we do
to cameras our photographers dunk in salt water. We avoid
using WD-40 because of its residue's unfortunate tendency to
accumulate and trap dirt, which isn't good for the optics or
the recorder mechanism.

No reason I know of why it *has* to be internal. Just build it in a
small (plastic) box with its own battery and put it close to the SW1.

Source record: 107678
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.swap

I'm looking for a pair of Collins (or equiv.) mechanical filters for a CW receiver which I'm building. I'm planning on using one of the filters in the front of the IF and using another in the "tail-ended" mode after the last IF amp. The filters should be the same frequency with the tail-ended filter 100 to 200 hertz wider than the first filter (this was recommended in a book by Doug DeMaw although the same bandwidth should work as well if the filters have the same frequency).

If you have any of these critters, drop me a note with specifics such as part number, bandwidth and price.

I would also like to hear from anyone else that has used this technique in a home built receiver.

Thanks,
Mark

Steve.....

You might try our company (ICS Inc.) for VCO's. If you haven't caught one of our ads in Microwaves & RF or RF Design, we're one of the largest suppliers of surface mount VCO's in the
United States. We stock practically every model we have for sampling purposes, certainly in the
1-2 GHz range. And hey, you can't beat the price for samples (they're free!). If you're interested, you can contact me at our address below or send me an E-mail. Incidentally, below is
data from one our models. It's available in either a .910 or .5" package.

BTW, you mentioned that Mini-Ckts will not be delivering some of their models in the near future.
From what I understand, they work real well, and have ample supply. Are they going to an allocation schedule because of demand? I'd be interested in any info you have on that.

Message-ID: <kaboom-2701962318100001@arcade-slip21.dynamic.usit.net>
Source record: 107760

I just acquired a Non-Linear Systems MS230 mini oscilloscope at a hamfest. The thing works, but it has an oddity I can't figure out. With the trigger set to "internal," everything works as it should. When I set it to "auto," it free-runs, as it should. But, then it will not sync to a signal at all... it just continues to free-run. I went through the scope and tested and/or swapped out just about every semiconductor in it (luckily, the ICs are in sockets, and are common CMOS). Nothing helps. Anybody have one of these things? Is it possible it was designed that way? Anybody have a schematic for it? Please reply via email, and thanks for any help you can give me. For that matter, is NLS still in business?

Michael

749. Help: MS230 Mini o'scope

Newsgroup: rec.radio.amateur.homebrew

From: kaboom@usit.net
Message-ID: <kaboom-2701962320290001@arcade-slip21.dynamic.usit.net>
Source record: 107761

I just acquired a Non-Linear Systems MS230 mini oscilloscope at a hamfest. The thing works, but it has an oddity I can't figure out. With the trigger set to "internal," everything works as it should. Of course, the trace goes out when the trigger is not locked. (It's supposed to do that.) When I set it to "auto," it free-runs, as it should. But, then it will not sync to a signal at all... it just continues to free-run, making the auto function useless. On all other scopes I've ever used, auto will make it free-run when unlocked, and then it reverts to a locked condition when the trigger syncs to the signal.

I went through the scope and tested and/or swapped out just about every semiconductor in it (luckily, the ICs are in sockets, and are common CMOS). Nothing helps. Poking around with my other scope turned up nothing, either. Anybody have one of these things? Is it possible it was designed that way? Anybody have a schematic for it? Please reply via email, and thanks for any help you can give me. For that matter, is NLS still in business?

Omega Engineering makes thermally conductive epoxies. I suggest
getting their catalog since they have a few different types. They are
very good at responding to queries.
Phone: (800) 826-6342
Fax: (203) 359-7990

You might want to check out Thermaloy (214) 243-4321 or
Wakefield Engineering (617)245-5900. One of them also make a
thermally conductive epoxy.

754. 82 Repeater in Kansas City

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-28 00:00:00 UTC
From: george@sky.net
Message-ID: <4efpb3$pt2@alpha.sky.net>
Source record: 107766
Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.digital.misc

Well its happened.We the club members of the 82 repeater in Kansas City are dam mad.We didnt get
to vote and we didnt get to talk before the board decided to shut down the repeater between the hours
of 11 pm and 5:30 am.
There is over 600 members and these member are told that they can use the repeater because of one
person that misuses the repeater.This person has made it a living hell for all of us.So the club does this
and thinks that members will just say ok.On top of that the FCC is no help at all.They dont give a dam if
ham radio looks and sound like the cb band.And the old timers just say"Nocodes are the problem"
Well I give up.I dont know what to do anymore.I wonder why I got my ticket.And as I see it the hole
hobby is going down the drain.Im going to just call the ham band the chicken band radio.
And to Rick and all of the people that act like Rick.I hope that you are happy with what you did to the
82 repeat in Kansas City.
To the FCC I think that they should fire the lot and close the door.They are worthless.

Please do not reply back because I just dont give a care anymore.....

For the rest of you out there that love ham radio,I wish you good luck.

On the 146.85 repeater here in Central NY we had trouble with one user also. He made it that
no one would even monitor the reapeater anymore. The club voted to ban him and we did. The reapeater is a great place to be again.

Hello dr. Om's,

I need a power module for 23cm (1299 Mhz) applications
I'm running here the PI1GTB interlink station for TCPIP packetradio in the
Southern parts of the Netherlands...

For this pupose i'v build myself an Interlink-I sem-duplex tranceiver (german
design). The outputpower is only 600 mW

I'm now looking for a power module and schematics to build a little amplifier
for say 3 to 5 watts on 1299 Mhz..

Who can help..

Thanks for reading

That's a weird story. The jerk behaves badly enough to be banned but is
obedient enough to obey your request that he voluntarily not transmit on
the legally licensed (input) frequency. Were there some strong words of
`encouragement' that went with the banning?

Regards,

There is a good article on adding a BFO to an AM transistor radio in the August 1985 issue on QST Page 34 ... try your local library for a copy of the article.

I want to add a BFO to the tiny Sony SW1 .... first, I need to get hold of a copy of the schematics ...<sigh> guess its another $15.00 to Sony for the service manual. I don't know if I will be able to fit the above circuit into the radio, because it requires a FT-50-43 toroid core and an IF transformer.; might be too bulky.

Thank-you for reading this. My name is Michael Long (KB8WPE) and I am the Public Relations Manager for the Husky Amateur Radio Club (HARC) whose callsign is W8YY. The club is located on the Michigan Technological University campus.

Starting on February 1, 6am EST, and continuing on until February 3, 6am EST, W8YY will be running a Special Events station for Michigan Tech's Winter Carnival '96. The frequencies listed below are the most likely place we will be operating. For this Special Events station we have 8"x11" certificates that would look great on anyones' wall! All you have to do is contact us and then send a QSL with a self addressed stamped envelope to receive the certificate.

Here are the frequencies:

Band Frequency Mode Time
160m 1.90 MHz LSB 8pm-8am
75m 3.90 MHz LSB 10pm-8am
40m 7.25 MHz LSB 7pm-10pm
20m 14.250 MHz USB majority of the day (8am-7pm)
17m 18.150 MHz USB if open 8am-7pm
15m 21.350 MHz USB if open 8am-7pm
10m 28.40 MHz USB if open 8am-7pm
2m 144.2 MHz USB All the time
146.58 MHz FM All the time
70cm 432.100 MHz USB All the time

Again, thank-you for reading this message and all of us here hope to here from you during the Special Events station!

For any more info. email me at cmlong@mtu.edu or the Club President, Dave Gillahan, at dmgillah@mtu.edu

You can also check out our homepage at
http://techsrv1.tech.mtu.edu:8080/harc.html
Though it is just beginning it does have a little information on it.

Sincerely,
Mike Long -KB8WPE-

I just bought a fax data voice switch that is supposed to answer the fone and route the call for me. It needs more ring voltage than what the phone company says they can provide. I have about 75-80 volts and the unit needs 100v to work right. Does anyone have any Idea how I might be able to boost the ring voltage legally and without harm to my equipment? I have not ever heard of anything commercial but would go that route if you know of something. Thanks for reading and please e-mail me with any replies. Also please don't flame me for this post not being related close to Ham Radio, being around Hams for 25 years I know that they are a bunch that might have a solution.

The suggestion to soak dirty rigs in warm water with bubble bath raises a question I've wondered about for years. I recall reading a Tektronix service note years ago, in which dirty Tek scopes were washed out with warm soapy water, rinsed, and air dried at a warm (100 degree) temp for a day or so. If I recall correctly (I read this about 30 years ago), the xfmrs were removed, and afterwards the paper caps were replaced, and switches lubricated.

I've never had the nerve to try this technique. I just can't bring myself to dunk, say, my Central Electronics 100V in the bathtub and let it soak. I'd be interested in knowing others' experience with this cleaning method. Is it really necessary to remove the transformers? What happens to the cardboard sleeves of IF transformers? Does it hopeless ruin paper capacitors? Are there other precautions to take?

The Super Keyer II is referred to as the K-1 Logi-Key
these days. It's a fantastic invention! I built the
November, 1990 QST version back then, still have it,
no problems ever, only needs batteries changed about
once a year, and I use it heavily.

This is such a good design that Kenwood included it
in the new TS-870S as standard equipment, with six
pages in the manual telling how to use it.

Wonderful device! Gotta have it!!

I asked this same question a few years back. I was told that Harly Davidson dealers can order black Crackle paint that should be exactly what you want. Note that you need to do more than paint it on. It needs to cure in an oven and I can't comment on that. If you are an ARRL member you might want to contact Member services and ask for any old pieces on doing this properly. I just know some old QST bit has to talk about this. BTW I've got an old J-36 Bug (WWII Era) that some nut painted lime green. I'm going to figure out how to do this as well. Just don't know when I will have the time,.

>
> Ed ecgallup@mlode.com

Most good hardware stores carry an extensive line of spray paints,
including wrinkle finish black. Try an Ace Hardware, True Value
Hardware, or Home Depot. I prefer Krylon brand but there are others.

One trick to getting a good wrinkle finish is to make sure the item
to be painted is warm, and warm it further after painting. I sit the
object on top of the boiler jacket (about 120 F) of the buidling heating
system. In about 45 minutes to an hour, you'll have a nice wrinkle finish.

One caution, for some reason only black gives a good wrinkle finish.
If you want a different color, get the wrinkle with black, and then
top that with whatever color you want after the black dries and wrinkles.

You can do this yourself, and get great results! The
paint is sold at auto parts stores in spray cans. I
use it frequently to paint radio cabinets and such.
Baking isn't necessary if you wait 'til the summer
and let the painted item sit in the hot sun for a few
hours (works well in 100 degree Texas heat!). Much
of the time, I don't even strip off the old paint,
because the wrinkle finish is thick enough and coarse
enough to hide imperfections in the old base coat.

Be sure to read the directions on the spray can!

Good luck!

>happens to the cardboard sleeves of IF transformers? Does it hopeless
>ruin paper capacitors? Are there other precautions to take?

Paper components can be a problem. They swell when wet, and won't
go back to their original dimensions when dried. If the paper wrap
of a power transformer is well varnished, it may not swell, but there
is a risk. Paper capacitors, and electrolytic capacitors with paper
sleeves, will be ruined. The tuning scales on some old radios are
paper based, and they can be ruined too unless they are heavily
oiled or waxed.

The bubble bath method works well on modern equipment, which has
little or no paper components, and warm water is about the only
thing that's effective if salt water has been in the equipment,
because you've *got* to get all the salt out or you'll have
continuing corrosion problems, and besides, the salt water would
have ruined any paper components anyway.

I've put old WWII equipment in the dishwasher. Dishwasher detergent
is really harsh, but boy does it clean well. You're going to have
to replace the old paper capacitors in that equipment anyway, just
due to age, so that's not much of a concern. And the hot water will
soften or remove wax that may be used to seal adjustable coils, but
the rig will probably need an alignment anyway, so that's not a big
concern either. But the dishwasher detergent can etch aluminum, and
aluminum parts can come out frosted instead of shiny, so you might
think about that before pitching that old radio in the dishwasher.
Any bare aluminum parts that will show should probably be removed.
Painted or anodized aluminum is Ok to put in the dishwasher. Steel
parts will do fine too, just don't use the dry cycle. There's heat
and humidity during the dry cycle that'll rust bare steel for sure.

Take the radio out after the wash cycle, blow out all the water
you can, and leave the radio in a warm low humidity place overnight
to finish drying (a very slightly warm oven can be used to hasten
the process, but don't overdo the heat).

Ed Gallup (ecgallup@mlode.com) wrote:
: Can anyone advise where wrinkle paint may be obtained, (such as black
: or gray), or how it may be made. Thanks.

PEP Boys "Manny, Moe, and Jack" automotive stores sell black wrinkle finish spray paint. It works fine. But follow the instructions on the can for best results.

The manufacturer and part number is:

plasti-kote Wrinkle Finish
No. 217 Black

plasti-kote Co. Inc.
Medina, Ohio 44256

As I recall, several other colors are also available. If you don't have a PEP Boys nearby, then a hobby shop, paint store or hardware store could probably order it for you. It is not expensive, about the same price as any spray paint.

Jim,
I'm with you in regards to dunking. But back in the
1950's I watched my father wash out radio chassis's with mineral
spirits followed by soapy(Tide) water. He never dunked them,
used a paint brush & quick rinse. He would also set them in the
sun for a few days before reassembly. These were ones he
purchased, fixed & resold.

I now collect some of the same type that he did that to,
but I don't think I will ever wash any of mine that way.

Thanks for reminding me of the memories....

Never tried it with a scope. I have tried it with an 8 track tape player
(in their heyday) whose owner had tried to improve the grip of the rubber
belt drive by liberally smearing it with honey. Naturally, it crystallized
into a very hard lump.

I soaked it for several hours, shook all the water off, and let it air dry
in a stream of warm air from a nearby cooling fan for several days. After
relubrication and a new belt, it was fine.

I'd only do this if there was no other way to clean it, and removing the
transformers is certainly advisable on AC equipment.

>in a home built receiver.

Haven't used Collins filters but have used 9 MHz KVGs in this application. (XF9B input, XF9A output) I know there is a theoretical advantage to having the second filter, but I didn't note much improvement in my HB receiver. There can be a complication in the AGC system though. After conversation with Wes Haywood, I decided to move the AGC pickoff ahead of the second filter. The time delay through the second filter was causing severe AGC pumping. See KN5S's article in a recent QEX for more on this.

Assuming no i-f overload and a decent product detector, you basically suffer no more than 3 dB extra noise at the audio amp without the second filter. Of course if the first filter has poor stopband rejection or there is leakage around it, the second filter can help.

Good luck,

Wes -- N7WS

>you do that?

Go to the Arizona Repeater Association's Home Page to see how this is done. It involves actively pursuing people who engage in such activity. The ARA, as a matter of routine, has an interference committee dedicated to tracking these people down.

Despite reports to the contrary, the FCC does frown on this activity, and will enforce sanctions. Just ask the people here in Phoenix about that. An NAL, Notice of Apparant Liability, carries a stiff monetary fine, about $20,000 (US) worth and forfeiture of ALL broadcasting equipment and license(s).

It has been reported to me, by Dan Ford, Commander of the SHERRIF'S Ham Radio Posse, that they also plan to actively engage in pursuing people misusing radio gear in Maricopa County. I strongly suggest that if you plan on jamming a repeater in Central Arizona, plan on getting caught.

Unfortunately, the ARA has had, for the 3rd time its existence, had to remove a member, by board action, for misconduct involving repeaters. This "gentleman" is also facing stiff legal sanctions from the FCC.

In 1995, the 3 biggest abusers of ARA repeaters WERE caught, and several others have been identified.

Too much broadband IF gain can deliver enough noise power to overload the product detector and cause unwanted (>2nd-order) intermodulation. The effect is that additional noise becomes mixed with the signal, degrading the SNR way beyond the expected 3dB.

This is a similar effect to the one mentioned some weeks ago in the discussion about measuring filter performance using a broadband high-power noise source and a spectrum analyzer. Except when limited by a narrow bandpass filter, the total integrated noise power overloads the analyzer so that the filter stopband fills up again with intermodulated noise.

In an IF amplifier, even a very moderate amount of post-filter selectivity (simple tuned circuits) is usually enough to chop down the broadband noise from the earlier stages. This makes a big improvement to the SNR without introducing delays which could affect the AGC. In other words, you can have the best of both worlds without the expense of a second mechanical or xtal filter.

Bring back IF transformers!

It's probably in the neighborhood of 5000 ohms, if you want a starting
point for experimenting. They typically require a few pF. (may be negative
or positive) of shunt capacitance as well. Be sure to have 2 adjustments
on each port, so you can do both R and C.

>know nothing about grounding.

It is very possible that you are getting EMI into your radio from the computer AC line. Locate some large toroid cores and wind 6 to 8 loops of each AC power cord through one. Try your setup again. You MAY be getting the oscillation through the ELECTRICAL ground loop you created between the computer and the radio.

Grounding at any frequency should be kept to the shortest length possible. The ground wire can act as the missing half of an antenna and actually radiate/receive signals, especially if it is 1/4 of a wave length of an operating frequency long, or longer.

Make sure you use an EARTH ground. The electrical pannel ground bus is better than nothing, but nothing beats an earth ground.

I've had these same problems and I have reduced almost all of my computer EMI problems. The only band I have problems on is 15 meters! No VHF/UHV problems!

The only EMI/RFI problems I have is with my burgler alarm. It keeps going off and the police have to respond. I only have trouble on 10, 12 and 15 meters.

I'll get all this figured out, someday.

I agree with Ian. In my previous post, I neglected to mention the assumption that the i-f strip included some moderate tuned-circuit selectivity. As to the reduction of hiss (over and above the image sideband noise) I fail to see an advantage to the second filter, give my earlier assumptions. The product detector is just another mixer which can be followed with an audio BP filter (doesn't have to be DSP) to achieve the same BW reduction as the second mechanical or crystal filter. In other words, except for the fold over of the image sideband, you can't tell the difference.

As to audio DSP, I must confess to being underwhelmed with my DSP-9. I consistently find that I'm using the 1.8 KHz BW even on EME strength CW. A trained ear is still a lot better (IMHO) than a box full of electronics. In the absence of QRM, I just don't see the necessity for "brick-wall" filters. A couple of synchronously-tuned passive LC circuits and a good pair of hi-fi phones work fine. No power supply, no hum, no hiss, no crossover distortion, no cost:-)

I had similar problems some years back using a homebrew computer. What I did was to use a noise-cancelling circuit.

What I did was to erect a short aerial next to the offending equipment and connect this to one end of a loop. Then connect the main aerial to the other. By using a potential divider and variable capacitor I could use the noise picked up on the short aerial to cancel out the noise being picked up on the main aerial.

| RX
1000 ohm R C
R C
R C 200pf Variable R and C in parallel
|
|
Ground or nearest copper water pipe!
```

I hope the 'diagram' is clear.
By careful adjustment of R and C it was possible to "phase" out most of the noise. The circuit did need adjustment if large changes in frequency were made.
This circuit was also helpful in reducing TV Timebase interference on 160m.

Hope this is of interest.

The sort of "grounding" you're contemplating is mainly a DC or very low frequency AC ground which can help you safety wise but will do little if anything for your RF interference problems. You somehow neglected to mention what type of CPU you have but many of us have had good luck using the "RF-absorbent" spray paint available at Radio Shack and other electronics suppliers. On most computers, removal of the plastic housings and spraying a coat of this rather expensive but effective paint will knock down your interference some 20 dB or more. Using ferrite clamps and kits to pass your computer cables through also can help. Getting your antennas as high in the air and as far away from the operating / computer position helps, as well as experimenting with minor relocations of equipment in the radio room to minimize interference on desired frequencies.

805. PTO Temperature Compensation

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-30 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <823084973.2216@pinetree.microserve.com>
Source record: 107637

I have four identical PTO's in solid-state rigs that I've been trying to stabilize, with only limited success. Maybe someone with more experience in this area can help me out.

First, the oscillator is a JFET in the usual Colpitts configuration, operating from 5.0-5.5 MHz. From the factory, the two feedback capacitors are each 91 pf silver micas. The inductor is paralleled with approximately 140 pf. The latter is composed of three separate disc capacitors, ranging from N220 to N330 types.

The problem I have with the PTO's is that they all drift upward as the temperature rises. Following a ten or fifteen minute warmup, I tracked the drift over a five or six hour period as the chassis of the rig(s) gradually warmed up. The first PTO (which probably had a bad component) would drift about 1.6 KHz. The second PTO drifted about 800 Hz, and the last two units both drifted about 300-400 Hz.

I decided to tackle the worst ones first, and I began by replacing the oscillator transistors with MPF102's. This helped considerably. Next, following many, many hours of trial and error, I ended up replacing the silver micas with 100 pf polystyrene capacitors, and the remaining three compensation capacitors also with polystyrene units.

Now the first two PTO's drift upward almost an identical amount, about 200-300 Hz during the same warmup period. This may not sound like much, but the problem is that when the rig is used to transmit, chassis temperature quickly rises another 10 or 15 degrees. This causes another drift to take place during the first hour or so of a QSO, and the drift amounts to approximately 200-300 Hz. This occurs in addition to the longer-term warmup drift, and it takes place no matter how long the rig is powered on prior to the QSO.

One of the things that seems odd about this has to do with the capacitors I tried. First, as I gradually replaced the N220 and N330 capacitors with polystyrene units, the upward drift diminished. This has made me think that the PTO's were, in fact, over-compensated. Now, it's my understanding that polystyrene capacitors also exhibit a negative temperature coefficient, and that the coefficient is not particularly well controlled. Mallory states pretty wide variations for their capacitors, ranging from about -50 ppm to about -175 ppm.

So, thinking that the PTO's were still over-compensated, I went back and replaced about 100 pf in one of them with NPO discs. However, rather than reducing the drift further, or causing a downward drift, this merely caused the initial extreme upward drift to return.

There's not much left for me to do, other than trying to find some type of linear, positive-coefficient capacitor. Mallory does manufacturer them (disc type SL), but they're apparently difficult to come by. Also, I've already spent a considerable sum on polystyrene capacitors and I'm reluctant to buy additional specialized capacitors after my results with the NPO's.

If anyone has any suggestions or can point out an error in my thinking on this work, I would certainly appreciate it.

73,
Jack WB3U

806. Shielded Capacitors

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-30 00:00:00 UTC

Source record: 107638

I'm working on a problem that requires small, shielded, PC-mount bypass caps. I need values around 0.1 and 0.05 uf, and the capacitors need to be constructed in such a way that when the "negative" lead is grounded, the inner case of the cap will prevent the "hot" side from radiating.

Can someone tell me if any of the inexpensive monolithic or tantalum capacitors are constructed this way? If so, will 0.1 uf tantalums provide satisfactory bypassing at 9 MHz? Any suggestions for other (affordable) types that will do the job?

That's a good 8-pole, 2.4 KHz filter. It was used in quite a few
models of Swan and Swan-related gear, including the Astro 103 that
I own. I don't need a new filter at the moment, but could I convince
you not to play with that particular component? They're not made
anymore and someday, someone might have to trash their rig for lack
of a replacement.

Just my $.02. :)

Hi Allen, I am just about ready to place a Argo 556 for sale.
The rig is a low power version of the current production Scout, except 5 watts out. Comes with several modules, and a slight problem. On CW all OK, on SSB, small amount of side tone comes out of speaker. This is not heard on the transmit audio, but it is still there. I use a keyer with a builtin sidetone, and have turned this down, but it is there never the less. I will ship for $325, with all the modules. Call me if you are interested in it. I am looking for help with modifiying the vocabulary or our
repeater's voice synthesizer. Is there anyone out there that
might be able to point me in the right direction regarding TI
voice synthesisers?

Specifically, I am looking for information on converting digitized
audio to LPC-10 code. Software that runs on a PC and uses .WAV
files or the like would be ideal.

Also, another option is to extract phonems from the current ROM
and recombine to create the new words that we would like to have.
Does anyone have a good phonem dictionary?

Any other help or insight would be greatly appreciated. Thanks
in advance for any help.

Technical solutions do exist. Using a "TX-ID" board, which uniquely
fingerprints each transmitter and a PC one can "slectively" include or
preclude individual users.

The board was not meant for that purpose, but with just a little Basic of C
codes, it workd just fine. It is especially easy if you have a single or
limited number of receive site.

Good luck and Have fun.

Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew

I'm looking for information from anyone who has developed a technique for transferring CCITT group-3 fax (i.e., standard office fax machine data) via radio. The "ideal" system would be one wherein a person at point A stuffs a document into a fax machine and it comes rolling out of a fax machine at point B, with the connection between the points being a radio link. But I'm interested in *any* techniques being used to achieve fax-via-radio. (Note: NOT WEFAX, APT or what-have-you. Just G3 fax!)

Thanks.

I used WD-40 to fix my 1957 Chevrolet when the alternator went bad.
I had been driving down the highway when the ignition light came on and
smoke poured out of the hood. There was a very bad burning smell.
All I did was dip the alternator in WD40 and blowit out a few times and
it was as good as new.

The following week, the engine threw a rod. I pulled the valve cover off
and sprayed WD40 into the engine and blew it out. I repeated the process
three times and after that everything was fine. Later that week, the car
broke an axle. No problem. I just sprayed WD-40 on it and the axle was
fine after that. Yup, it sure works for me!

Hi Dean, Dean here...

I have built two of the NN1G rigs which _were_ sold by Danny Stevig
(but I'm not sure he's still in biz). They work very well, and are
cheap (around $50). I believe there is a 30m version (I built the
20m and 40m versions). My 20m version was featured in the July '94
issue of QRP Quarterly.

I have built the NE-4040, also a NN1G design. He sells this kit
himself. It, too, is quite cheap (around $50). I know for sure
that there is a 30m version.

If you have a receiver that picks up 30m, try building up the
"Modified Cubic Incher" transmitter (see recent ARRL Handbooks).
I built one for 40m and it works fine. There is a 30m version
detailed in the article (same design, coil/cap changes only).
Requires fundamental frequency xtals.

Not sure about the other kits. They all seem a bit pricey,
but that's just my humble opinion.

The QRP Plus is neat, but... GEEZ... it costs B-I-G buxx!!!!!!
I played with one at a hamfest in 1994, and it was pretty
impressive, but I hear their service is only so-so, and the
rig is somewhat trouble-prone. This is hearsay only, so if
anyone has a different opinion, don't flame me!

Do you own a solid-state HF rig? Try turning the RF output
down to QRP levels and do some QRP band-blasting that way.
I've been doing it for years. Actually, all I run is QRP
CW, no matter what rig I'm using. My TS-870S makes a great
QRP rig because of its incredible receiver (you can't work

'em if you can't hear 'em!).

Good luck... 73 / 72 de KC5NG

>

The second filter eliminates noise from the other sideband (thus
the 3db improvement) and eliminates the hiss. One can see a diffrence
it makes when one compares CW reception with 1st IF with 2nd IF
filters. Disregarding differences in slopes, the 2nd IF filter cuts
the hiss and makes the signal sound more "professional". One can have
a similar effect with a DSP, but good DSPs are not cheaper than
the 2nd IF filter and the 3db advanatage is lost.

I'm sure you're joking or just fishing for flames, but you
really CAN "work Russia" with a handheld radio. If you happen
to live in south Florida or Northern New Mexico or Southern
California or the Wasatch Front in Utah or other of the several
areas having publicly available crossband remote base /
repeater systems you can get user touchtone command lists from
the owners/sysops and work DX via HF remote base from your
walkie-talkie. You'll need most likely a dual bander with PL
memory functions to enjoy both local area contacts with 2
meters and the DX and other fun stuff available through your
nearest 220 or 440 remote base system. You should ask around
your area before buying. Rarely are 2 meter repeaters set up
for such exotic remote base functions (to be legal they have to
be controlled via 220 MHZ or higher frequencies) but I know in
South Florida at least one system is set up so that users can
talk out on HF SSB with a 2 meter FM radio only, no UHF
required. I've talked to them several times with MY
handi-talkie using MY remote HF base system from here in NM.
Keep in mind, now, that depending on your license, you will
need to have a control operator on duty for you to legally talk
through a remote base from your VHF/UHF rig on a particular HF
frequency. You will not be able to just dial up 20 meters, for
example, unless you have a general or higher class license. A
properly licensed control op can dial it for you and let you
talk under his "remote supervision", so it isn't normally
something you can just do on the spur of the moment without
the proper license but it's still fun.... and gets even more
fun as you upgrade so you can also become a control op.
If you by chance happen to live in northern NM I'd be happy to
email you a list of our system's touchtone users commands.

827. Does bubble bath ruin paper caps?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-31 00:00:00 UTC
From: tiemann@spot.Colorado.EDU
Message-ID: <4emhhj$c8s@peabody.colorado.edu>
Source record: 107643

I've never (intentionally!) washed out electronic equipment with soapy water, but the question whether this hoplessly ruins paper caps has arisen.

I say they're probably already ruined, even before getting washed! (Even if the thing they're in works just fine.)

I discovered two interesting things about paper caps. First, when posed with 30 volts, many had measurable leakage currents, implying leakage resistances in only the few hundred megohm range, making them totally unsuitable for some applications, and second, that some charged and discharged in a visco-elastic sort of way, in that the charging current only slowly went to zero with continued application of constant charging voltage, and then when the thing was disconnected from the charging voltage and shorted out, the voltage shot back up again in a rebound. The worst offenders were all paper caps, and some rebounded back up 7 or 8 volts when offered 30 volts and then shorted momentarily.

This isn't a hazard at the 30 volts I tested them at, but what about at the 400 or 600 volts they're rated for? They'd rebound some 100 volts - no good! I discarded them. Some of them rebounded back to 2 volts after being shorted for the second time, and were still at 2 V two or three days later.

Ceramic caps had no measurable leakage current by my simple VOM, and hardly 100 mV of rebound voltage at most. They're smaller too, and probably have lower ESR as well. 0.047 uF @ 2 kV discs are $0.15 each at the local store.

I see no need to worry about the detrimental effects of soap suds on paper caps; I'd worry about them as they are!

I'm working on a problem that requires small, shielded, PC-mount bypass caps. I need values around 0.1 and 0.05 uf and the capacitors need to be constructed in such a way that when the "negative" lead is grounded, the inner case of the cap will prevent the "hot" side from radiating.

Can someone tell me if any of the inexpensive monolithic or tantalum capacitors are constructed this way? If so, will 0.1 uf tantalums provide satisfactory bypassing at 9 MHz? Any suggestions for other (affordable) types that will do the job?

>all else fails.

That's a good 8-pole, 2.4 KHz filter. It was used in quite a few
models of Swan and Swan-related gear, including the Astro 103 that
I own. I don't need a new filter at the moment, but could I convince
you not to play with that particular component? They're not made
anymore and someday, someone will probably have to trash their rig for
lack of a replacement.

On the other hand, if you're really determined to do this, send me
some e-mail. I'll outline the details of the circuitry surrounding
that filter in the 103. It will undoubtedly save you lots of cut and
try.

You might want to try the JPS ANC-4. Unlike other DSP's, it goes in
the antenna lead and is designed specifically for local noise.
According to what I've read in the newsgroups, it's remarkably
effective. It was tested in the latest issue of QST.

I wonder if someone can help me with data on SRFH1900 wich is a final
transistor in REALISTIC HTX-202. I need to find a substitute for that one.
Another problem is a final device in ALINCO DJ-160. It is marked as

M57796H
05SJ

What that one can be substituted with. What is the data for that one.
You see, knowing data for both I will probably be able to locate Russian
equivalent.
And finally does anybody know of www site or other type of server were one
can search for particular electronic part and retrive tech data or get
to know where that part can be obtained.

A bubble bath may be the only way to clean the signal up an old boatanchor! (Just kidding Jim, I couldn't resist)

Seriously. I use a quick soapy water bath, a water hose bath, then a distilled water bath, then I use an airhose to blow em out, then I let the rig dry under a heatlamp for a few days, and last I put a light coating of WD-40 in the right spots. I did that to a Ranger, DX-100 and an Apache.

My rigs now look very clean and still work, only the signals are dirty.

Pardon my lack of stereo fundamentals.....

But does anyone know of a chip manufactured by Motorola, National, etc. that will take left and right stereo audio outputs (from say a C.D. player) and produce an RF carrier suitable for reception and demod. on any stereo receiver? If not a single chip, does anyone know of any articles written on how to build such a thing? I would think the hardest part would be generating the subcarrier (a PLL?), but I would like to see what other people have come up with.

>Just how does a description of building a bunch of kits and
>tying them together with a microprocessor controlled DDS board
>that has to be purchased from the author (or totally redesigned
>from the ground up) end up in QEX??

Jay: I kind of understand where you are coming from!! But I must say I enjoyed the article from the standpoint of that it got my "creative juices" flowing.....let me explain......

Over the last year, I have constructed an all band all mode dual conversion superhet of the w7ZOI original design...Very heavly modified by me to include diode switching of all filters and bandswitching electronically by pushing one button to sequence all bands and LED readouts of band position along with automatic sideband selection. Well , anyway my point is that truthfully I am an engineer wannabe that will never make the "total design from the beginning" engineer. But I feel I am 1 step above a techician !!!! And most important, I truly am having fun.

I have purchased the microprocessor kit mentioned in the article and look forward to adapting it to my homebrew receiver to replace the L/C vfo and provide digital readout of frequency and other goodies mentioned in the article.

Another thing that the article has done for me is that while waiting for the kit, I have been reading up on PLL and DDS so that when all is running well, I will have a good idea why....

well, that is "one reporters opinion" and I look forward to other responses to your message.

839. PTO Temperature Compensation

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-31 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <4enu4k$gom@crash.microserve.net>
Source record: 107655

I have four identical PTO's in solid-state rigs that I've been trying to stabilize, with only limited success. Maybe someone with more experience in this area can help me with this.

First, the oscillator is a JFET in the usual Colpitts configuration, operating from 5.0-5.5 MHz. From the factory, the two feedback capacitors are each 91 pf silver micas. The inductor is paralleled with approximately 140 pf. The latter is composed of three separate disc capacitors, ranging from N220 to N330 types.

The problem I have with the PTO's is that they all drift upward as the temperature rises. Following a ten or fifteen minute warmup, I tracked the drift over a five or six hour period as the chassis of the rig(s) gradually warmed up. The first PTO (which probably had a bad component) would drift about 1.6 KHz. The second PTO drifted about 800 Hz, and the last two units both drifted about 300-400 Hz.

I decided to tackle the worst ones first, and I began by replacing the oscillator transistors with MPF102's. This helped considerably. Next, following many, many hours of trial and error, I ended up replacing the silver micas with 100 pf polystyrene capacitors, and the remaining three compensation capacitors also with polystyrene units.

Now the first two PTO's drift upward almost an identical amount, about 200-300 Hz during the same warmup period. This may not sound like much, but the problem is that when the rig is used to transmit, chassis temperature quickly rises another 10 or 15 degrees. This causes another drift to take place during the first hour or so of a QSO, and the drift amounts to approximately 200-300 Hz. This occurs in addition to the longer-term warmup drift, and it takes place no matter how long the rig is powered on prior to the QSO.

One of the things that seems odd about this has to do with the capacitors I tried. First, as I gradually replaced the N220 and N330 capacitors with polystyrene units, the upward drift diminished. This has made me think that the PTO's were, in fact, over-compensated. Now, it's my understanding that polystyrene capacitors also exhibit a negative temperature coefficient, and that the coefficient is not particularly well controlled. Mallory states pretty wide variations for their capacitors, ranging from about -50 ppm to about -175 ppm.

So, thinking that the PTO's were still over-compensated, I went back and replaced about 100 pf in one of them with NPO discs. However, rather than reducing the drift further, or causing a downward drift, this merely caused the initial extreme upward drift to return.

There's not much left for me to do, other than trying to find some type of linear, positive-coefficient capacitor. Mallory does manufacturer them (disc type SL), but they're apparently difficult to come by. Also, I've already spent a considerable sum on polystyrene capacitors and I'm reluctant to buy additional specialized capacitors after my results with the NPO's.

If anyone has any suggestions or can point out an error in my thinking on this work, I would certainly appreciate it.

CBVSR1 was only done for Win 95 only as we only do 32-bit
programming now.
However, we released another 16-bit app called QRP HomeBuilder that runs on
Windows 3.1 in the spring of 1995.
QRPHB1 is exclusively for homebrewers and would be of no use to
"non-building" HAMS. It is freeware.

same sites (SimTel) - ftp.coast.net or oak.oakland.edu etc
path = Simtel/win3/hamradio/qrphb1.zip

This app is rather banal looking. It has no toolbar, statusbar or fancy graphics,
but we have had a lot of good comments regarding it's code.
It has a module called CoilBuilder, which is the father to the new 32-bit
coil program we just released.

NOTES FOR QRP HOMEBUILDER1:

There is a "hidden" bitmap schematic. Access it by clicking on the picture of the 3 element
low-pass filter in the SYSTEM Menu. This is a previously unpublished schematic given to
us by Wes HayWard.

Many users have e-mailed us , stating they want to to PRINT results screens.
Since QRPHB1 has no printing capabilities, you have to do it in a round about method.

<< METHOD >>
When you have a results screen displayed press the ALT and the PRINTSCREEN keys
simultaneously. This will capture the screen to the Windows Clipboard.
Exit or minimize QRP HomeBuilder.

Now, open the Windows PaintBrush program and from the Menu select EDIT and then PASTE.
You should have a bitmapped copy of your results screen present.
Then select the PRINT menu item. After printing, delete or do-not-save the bmp image.

Although this method is crude, it does work. If you have a third party screen-capture program you can always use it, otherwise the method described works fine.

There is a statement in QRPHB1 stating we will not post release notices of our QRP HomeBuilder series in the UseNet Newsgroups.
We thought about it and have "appended our policy" . We will only post FREEWARE program releases to the News Groups. It is our firm's belief that commercial interests of any nature for financial gain do not belong in the UseNet Newsgroups.

We presently, have no connection to the Amateur Radio industry whatsoever. The QRP HomeBuilder releases are released as freeware to promote electronics as a hobby and to give us something "fun" to work on; that is our reward.

Thanks Rod and Todly
Jenna Design

Eliot, there was an article in Radio Electronics some fifteen years ago titled something like "An FM Stereo Signal Generator" It used three or so common chips and a 19 KHz oscillator, which of course, was doubled and run through a 1596 balanced modulator to form the left minus right 38 KHz signal. I wish I could be more specific but that is a start, even if complete modulator chips are not available. Cliff Buttschardt W6HDO

The 3dB advantage isd in *IF* signal-to-noise ratio only - but the IF
noise should always be overridden by noise received from the antenna and
further up the RX chain. Unless the product detector is being overloaded
by broadband IF noise, you probably wouldn't hear the difference.

Wes again: *WARNING - TOPIC DRIFT :-)

>couple of synchronously-tuned passive LC circuits and a good pair of hi-fi
>phones work fine. No power supply, no hum, no hiss, no crossover distortion,
>no cost:-)

I love my DSP-9+ for EME (same filters as the DSP-9). Like Wes, I don't
find the brick-wall characteristic very useful when the application is
detecting weak signals rather than rejecting QRM. But the suppression of
noise on unwanted frequencies away from the signal tends to aid this
pair of trained ears. By concentrating harder I could probably switch
out the DSP filter and continue to copy in 1.8kHz, but it would break my
brain to do that for a whole pass of the moon.

Different folks, different filters - always has been.

By the way, in the latest 432 and Above EME newsletter, HB9BBD gives a
good preliminary report for the TS-870 on very weak signals.

Does anyone know of a chip that is used to demodulate multiplexed
signals such as FM sterio, secondary audio programming (SAP) on TV
sound and SCA on FM broadcast? I thought I could use my HF radio in FM
mode but I tried it and it didn't work. I finally figured out that
although the readout goes down to 0 hz it actually won't receive
anything less than 150 khz (the manual says so and I can hear the
relay click out.)
I'm sure there is a small, easy circuit to do this.

Feed-through caps fit your physical description, if you can tolerate have an end sticking through the other side of the board. I don't know about finding values as big as 0.1, though.

Hi Jack,
The cap behaves like a very small transmission line. The "shield" does nothing if it doesn't carry an equal and opposite current. Since that an impossible accomplishment with a two terminal component, the only solution is to keep the leads and component very short.

The biggest reduction in stray coupling or radiation would come from using a densely packaged cap, like a multi-layer chip.

It makes almost no difference if the ground foil is on the outside or inside of the component. The exception would be if the reactance of the bypass capacitor is so high compared to the circuit impedance that almost no current flows through the cap. But in that case it would be a poor bypass anyway! Catch 22!

>NOT WEFAX, APT or what-have-you. Just G3 fax!)

That's pretty trivial, Jon. All you need is a duplex radio connection
of telco grade. I've got that with the 902 MHz duplex radios I bought
off the power company when they switched to fiber. As far as the fax
is concerned, it's on a telephone line, and can train and transmit
just the way it does on the phone. The training cycle is the catch,
of course, and is why unmodified G3 fax can't be sent over ordinary
half-duplex channels.

852. Dec QEX "construction article??"

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-01-31 00:00:00 UTC
From: Jay Wicklund <jwicklun@mail.halcyon.com>
Message-ID: <NEWTNews.823110319.11656.jwicklun@mycroftxxx.halcyon.com>
Source record: 107668

Hi all, I just read my December QEX. Is anybody else out there bothered by whats happening at ARRL? The lead article sounded great "A Microprocessor Controlled Multiband Transceiver", but turned out to be of very, VERY limited value. I thought QEX was supposed to be an experimenters magazine - where people regularly build and modify equipment to try out new things. Just how does a description of building a bunch of kits and tying them together with a microprocessor controlled DDS board that has to be purchased from the author (or totally redesigned from the ground up) end up in QEX??

I have no problem with the author selling kits, but only after fully disclosing the design. What if I want to add some features, or some additional control outputs to drive some different or additional RF boards? If this was just all about building kits, then I guess that Heath would still be in business. I subscribed to QEX for the exchange of ideas and more technical design information than appears in QST; but this article doesn't do it for me.

What do you think?? Either way, if you're a QEX subscriber, let QEX (at qex@arrl.org) or the editor Jon Bloom (at jbloom@arrl.org) know how you feel. Maybe I'm the only one upset by this diversion into product reviews.

73 de KI7RH (Jay Wicklund)

853. Re: Dec QEX "construction article??"

Newsgroup: rec.radio.amateur.homebrew

From: randg@sps.mot.com
Message-ID: <4eoq1i$c8t@newsgate.sps.mot.com>
Source record: 107669

Jay Wicklund made some comments about our article in QEX, as though there was no way of reproducing the design without purchasing one of our kits.

We included in the article 100% of the board schematics -- what we omitted was the 179 page software listing, which was obviously inappropriate anyway.

The design includes a DDS which is controlled either from a knob or a keypad, and includes switching control to support anyone's RF modules to make up to a 10-band radio.

The bulk of the article most certainly is NOT a "kit review" as characterized by KI7RH.

> 73s,
> Mike Sims, K4GMH

I am just getting back to this newsgroup, and my intention was to post
a request for help on this same topic. Mike is ahead of me, but
I have the
parts to build a 4CX1600 amp except the actual tube and socket.
(Finding the
power transformer and the caps is the hardest part, I think.)
Anyhow, the
4CX1600 is a tetrode and the design specs I saw call for a
regulated screen
supply. It's not a big deal to design and include this but it
adds a little
more complication over the simple grounded grid design. But the
tetrode needs
to be cathode driven to prevent burning up the grids -- right?
Finally, did Alpha
do a simple GG design with the pair of 4CX800s in their Alpha 91 beta??

I could always fall back on the killer-demon tube: the 4-1000!
6kv and it flies!

Thanks in advance for advice from you true-blue design gurus.

(My only suggestion for Mike is to bring up the HV supply slowly
the first time you
turn it on, and if you have a big enuff variac that you can
leave in the line always
bring it up and down slowly.)

A Japanese company has a single chip stereo transmitter, the Rohm Ba1404.

For an example, see a construction article in Radio-Electronics magazine for July 1992 or one for the Ramsey FM-10 in Popular Electronics (date unknown, but more recent). A scanned version of the spec sheet is somewhere in ftp://dg-rtp.dg.com/fm10/archives/ .

Unless you want to deal with a fairly quirky chip, you can get a preassembled stereo to RF converter at your local discount store for about $20 in the form of the FX Wave Fx-100. Hanging on the pegboard in the audio department. (I use one hooked to my VCR for wireless headphones.) It's just LC tuned, but seems stable enough. The main chip has the label sanded off. It doesn't have enough pins to be a BA1404, but I suspect it is a related chip. I hear Rohm makes a stero multiplexer chip without the transmitter section. The FX wave has a seperate 4 transistor RF section.

>upset by this diversion into product reviews.

Perhaps surprisingly, given the howl I let out about the autotuner,
this article doesn't bother me. The main focus is on system integration.
There really aren't any novel features implemented by the uP, and the
code in it would only be of value if you were trying to integrate the
exact same set of RF kit modules the authors were using. The authors
do give the important algorithms used, as flow diagrams, and that's
sufficient since the detail implementation would vary depending on
what RF modules you used anyway.

What's important about this article is the *concept* employed to
integrate the complete transceiver, and that's adequately covered
in the article. That's a very different story from the autotuner
article where it was the algorithm that was novel, and hidden from
us. The L network wasn't anything special. In this case, the control
panel code isn't novel. I'd suggest that anyone who could understand
the source could implement his own version without it. The only novelty
here is the DDS, and that's been well covered recently in other articles.

Gary

I have some experience with this, so perhaps I can help a little.

: First, the oscillator is a JFET in the usual Colpitts configuration,
: operating from 5.0-5.5 MHz. From the factory, the two feedback
: capacitors are each 91 pf silver micas. The inductor is paralleled
: with approximately 140 pf. The latter is composed of three separate
: disc capacitors, ranging from N220 to N330 types.

much description deleted...

: If anyone has any suggestions or can point out an error in my
: thinking on this work, I would certainly appreciate it.

: 73,
: Jack WB3U

Your thinking is okay, it's just a very thorny problem to solve in
real life. Think of it in terms of PPM: at 5 MHz, a cheap crystal
oscillator (not compensated) will drift 250 to 500 Hz over temp. To
get better than that you need better temperature compensation.

What you need to do is find out what is drifting, how much, and correct
it (like you didn't know that, right ;-). That may mean that you
would have to measure specific temperature drifts on caps, and pick
particular caps. That may mean, say, getting several 390 pf, N330 caps
and picking the one with the exact drift you need. It's tedious, and
expensive. I've only been marginally involved with this sort of thing,
but I know it takes time.

Ideally, if everything had a zero TC, nothing would change, and I like
the idea of NPO (COG) caps everywhere. But if the inductor core is
what's drifting, your problem would get worse (I'll bet it is the
inductor).

Perhaps someone in the crystal business will tell you how they make a
TCXO, but the basic process is to match the exact crystal variation
over temp with an inverse variation in the circuit. You can tune a
varactor across the crystal with thermistors. The same approach may
work for you. You have to test the oscillator over temperature and
find out how much it drifts, then figure how much C you need to pull
it in, what voltage to drop in thermistors, etc., etc.. To do this
productively, like at a crystal oscillator house, you need to have

experience, good measurement equipment and probably curve-fitting software (I'd guess).

You could try a couple of other things they do in the crystal business to get around the problem. For example, if the oscillator drifts versus temperature, you can fix its temperature. Just make sure it is held higher than the level it will see during operation. (For example, if the circuit will see 130F, keep the oscillator at 140 or 150, just be sure to use some sort of thermostat). You can use resistors as the heating elements and wrap the whole thing in insulation. Another idea would be to lower the power output in the oscillator, to keep it cooler, and use an amplifier after it to get the signal back. If the problem is heat from elsewhere, though, this won't work.

Well, this is sort of vague, but I hope it helps.

73,
Bob

I found the artical very informative. It shows the way a micro is intergrated
into a xciver. It provides the info nessary for me to build a radio not only
with the kit parts but also intergrating other stuff. I am not a fair test
as I write software for a living, but it was clear to me how to do it.

If I choose to build one I would like to look at the source code if available
to see how they did. I would do it to suit me in the end anyway.

Keep up this kind of artical.

This is the basics to what Tektronix and HP equipment went through.
Couple added steps included baking in an oven at 135 degrees for
about 30-60 min. after the bath. The cleanser used was called 'Swipe",
and the currently marketed 'SimpleGreen' appears to be same stuff.
Of course all knobs and related parts should be removed and bathed
using an ultrasonic cleaner for best results - gets ALL the dirt out. You
may need to remark pointer 'dots' or 'lines' - tire markers work great,
and available in various colors needed (white, red, yellow, etc). One
point to watch - meters! Some aren't sealed and bathing is a problem
for them. Worth taking out and cleaning on the bench with a brush.
Also, keep a hair dryer handy - after blowing excessive water off, hit
with the hair dryer before baking. A lot of test gear valued well above
any ham gear received this treatment and was resold as 'reconditioned'.
Good luck.

Jack, in the your PTO temperature compensation problem there is something that is fundamentally wrong in that these units never have need for positive temperature compensation. In fact, if you were to remove the case from most any Collins PTO, there would be N100, N1500 and even N2200 ppm caps there! I would first see that there is no mechanical binding that would cause such problems. Secondly, I suspect that you are suffering from what I call "thermal delay"---that is the ability of the temperature compensating capactior to be in the right physical position to make timely change. This becomes especially critical in units where transmitting heat flows rapidly to the PTO. The only solution is to place the capacitor farther or closer to the heat source experimentally. With your call I suspect you have been around the barn as many times as I, so I will limit comment to this since it might well be a refresher!

The TA7204 is a common audio amplifier IC used in many types of
Japanese audio equipment, particularly automobile stereos. The chip
is still available, listed for sale at $10.44 from MCM Electronics.
MCM has a $20.00 minimum order, but will ship smaller orders with a
$5.00 service fee. Their phone for orders is (800) 543-4330.

Alternately, you might also try a few local stereo repair shops to
see if any of them stock this part.

Since a significant amount of the functionality of the project is
contained in that 179 page listing, why is it appropriate to
publish the schematics but not the firmware?

Is this firmware available in source form via SASE+diskette, or
via download?

WB3U (jackl@pinetree.microserve.com) wrote:
: I have four identical PTO's in solid-state rigs that I've been trying
: to stabilize, with only limited success. Maybe someone with more
: experience in this area can help me with this.

It's quite easy to have mechanical expansion effects spoil the
stability of a PTO. I've come across ones where it changed everytime I
touched them. Look critically at their mechanical design...

: I decided to tackle the worst ones first, and I began by replacing the
: oscillator transistors with MPF102's. This helped considerably.
: Next, following many, many hours of trial and error, I ended up
: replacing the silver micas with 100 pf polystyrene capacitors, and the
: remaining three compensation capacitors also with polystyrene units.

That sounds sensible: get rid of the compensation then use low tempco
components everywhere to minimise drift, finally compensate the remaining
drift.

: Now the first two PTO's drift upward almost an identical amount, about
: 200-300 Hz during the same warmup period. This may not sound like
: much, but the problem is that when the rig is used to transmit,
: chassis temperature quickly rises another 10 or 15 degrees. This
: causes another drift to take place during the first hour or so of a
: QSO, and the drift amounts to approximately 200-300 Hz. This occurs
: in addition to the longer-term warmup drift, and it takes place no
: matter how long the rig is powered on prior to the QSO.

Note that polystyrene capacitors should never be taken above 70 C as
they undergo a permanent value change

: There's not much left for me to do, other than trying to find some
: type of linear, positive-coefficient capacitor. Mallory does
: manufacturer them (disc type SL), but they're apparently difficult to
: come by. Also, I've already spent a considerable sum on polystyrene
: capacitors and I'm reluctant to buy additional specialized capacitors
: after my results with the NPO's.

You can go through a lot of components, also virtually nobody
nowadays uses controlled (non-zero) tempco capacitors, so finding them is
now virtually impossible. Temp compensated ctrstal osc manufacturers use
thermistors and varactor diodes.

Oxley used to make variable tempco capacitors for osc compensation,
but these are also like hen's teeth. I put a circuit for my favourite
easy-to-adjust thermistor based compensator in the osc chapter in the
1995 and 1996 ARRL handbooks.

Don't try compensation until you've weeded out any poor components, remember that if you have signifiacnt temp changes, you need to make your compensator and the thing that's being compensated heat and cool at the same rates or else you get drift during temp CHANGE and recovery after the change has stopped.

Cheers
David

My favorite cleaner/lubricant for potentiometers and switch contacts was manufactured by Daven. I believe that Daven and Shallco were the sole suppliers of ladder-type audio attenuators to the broadcast mixing console industry (RCA, Gates, Collins, McMartin, etc.).

I still have an original container of "Daven Oil" for this purpose and use it sparingly of course. It's got to last me a lifetime! Anyone else remember using Daven Oil?

Thanks for everyone's response. I'm learning and hearing that maybe the second filter is not the greatest idea but does offer some improvement? Let me ask the group, given the choice between a second IF filter and a DSP, all things considered, for only CW (weak signal work), which would you rather have or recommend? By asking the question, I've certainly gained some knowledge about the second filter, both pro and con. My primary goal is reception at LF with the emission CW (in a otherwise very noisy enviroment at best).

Rand Gray (randg@sps.mot.com) wrote:

I've not got that QEX yet, though I think I tried one out on my spectrum analyser at the famous QRP vicarage (chez G3RJV), courtesy of Sheldon Hands. Sheldon had his proto transceiver along at the G-QRP convention in October, and George G3RJV had bought a DDS unit from Sheldon as a Christmas present, which those of us at the Christmas party had a good play with....

Very, very, nice indeed.

One comment; I found a fair amount of processor related noise on the DDS output co-ax coming down as (mostly) a common mode signal. Having a transformer couple at one end of this cable, or else a ferrite sleeve balun helps. This is nothing serious, it's roughly equal to the level of the quantisation noise spurs, and might as well be eliminated as it's easy enough to do....

: We included in the article 100% of the board schematics -- what we
: omitted was the 179 page software listing, which was obviously
: inappropriate anyway.

It'd make a mess of QEX :-)

It comes down to coercion. If you make the code available, a few people will program their own CPUs, but the majority will opt for buying PCBs and ready-blown chips.

If you don't make the code available, you get loads of people upset about the lack of a choice that they would probably not exercise anyway.

What you don't want to happen, of course, is for someone else to take your released code and go into business flogging programmed parts.

As the software content of constructional projects is going to continue to increase, I think some effort is needed to find a way round this quandry. There have been some articles in QST where the code has been kept private, and programmed parts made available only from the author. No, it's not a matter of review articles, but I don't see how they are not single-sourced kits with their *assembly instructions* published in a magazine.

I don't know of any solution to this problem, but I can see valid concerns for both sides.

Cheers
David GM4ZNX

Dan Rockhold, AB7AS and Mark Sunders, KJ7BS are looking for a location in North Dakota from which to operate AB7AS during the 1996 ARRL November Sweepstakes.

If you are not a contester or know someone who is not a contester, and would be agreeable to having 2 guest operators for the contest, please respond!

We are in the planning stages for this expedition, but we need to get a location very soon.

We are interested in the station equipment, especially the antennas. We can bring out own radios, power supplies, computers and interfaces, if necessary. However, we can not bring the antenna farm, too.

The station owner is more than welcome to join us in out endevor, or just watch, keep up awake, or what ever. WE WANT YOU TO BE PART OF OUR TEAM. Our goal is NOT to win the contest, but to have a good time and gain new operating skills. From Dan's home QTH in Phoenix, AZ, we got all but 7 sections in the 1995 November Sweepstakes. We do have a lot of fun with this hobby.

If you are interested, or know someone who is interested, please contact me or Dan at one of the addresses below.

I Beg to differ, the schematic of a dedicated microprocessor is
trivial compared to the software that operates it. Even if you
don't feel that the entire program can be included, a complete
and detailed flow diagram can be. In addition there are sites
available including the arrl web page where additional files
can be downloaded for those that are interested.

Is that using some public key encryption technique?
If not, what is preventing the malicious from cloning one of the
apparently valid codes?

Also, what is preventing the malicious user from just keying up over
other people's transmissions, thus rendering the repeater useless?

Hmmm... it looks like HDTP (or equivalent of the FCC) does not put
out such drastic sanctions.
Normally one will lose the license for a year or so, and one could get
a fine of maybe $500.

This does not seem to stop some people... when you have been reading the
BBSes, you can see that the wellknown person that causes havoc on the
local packet network is still active. He is fully known by name,
ex-callsign, and address.
(he just uses callsigns of other people, mainly VERON officials, to
post offensive messages. he was also active on the phone repeater sometime,
transmitting over those same people, but I think he has lost interest in that)

Cliff:

I found an article in Radio Electronics from March 1988 that details the construction of a stereo xmitter. From what I've read in the alt.pirate.radio group, Rohm makes a chip (BA1404) that does much of the same thing and is available in an FM kit (FM10 or FM25) from Ramsey. Unfortunately, most of the responses indicated that the performance was lackluster. I downloaded the specs. on the chip, and it has decent channel separation (45 dB) so I don't understand why it should perform poorly.

The problem with print density within filled areas is a clasic problem with laser printers. The best solution is to use the transparancy material recommended by the printer manufacturer. They have put a lot of time into making sure that the printer and the media work together.

Every radio has a "unique" pattern when you key it (due to differences
in the components etc), this pattern can be used to identify a radio.
There is no encrypted signal or anything that fancy.

One of the repeaters that I used to monitor had a tx-id system on it,
if you ker-chunked the repeater more than 3 times in a 5-10 minute
period, it would lock you out for a couple of days. It was also used
to track stolen equipment (you had your tx "fingerprinted", then when
the tx got stolen, you just let one of the ops know and the repeater
would advise you when it heard that tx (if it heard it)). They, also,
could (and did) blacklist certain radios.

>Also, what is preventing the malicious user from just keying up over
>other people's transmissions, thus rendering the repeater useless?
>

This is one of the weaknesses of the system, another is changing the
rig, or swapping a couple of components in the tx (changing some of
the resistors/caps is usually enough).

If someone really wants to get around the system they will.

regards,
Dean.

I don't think any of the modules you mention have varactor diodes in them.
Motion detectors, which are just simple doppler radar implementations,
don't need varactors and would just be more expensive. What you probably
want is a full blown Gunnplexer. Be prepared to pay the price!

903. Interface information for LCD display

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-02 00:00:00 UTC
From: draagen@news.connectnet.com
Message-ID: <4etlph$qfo@news.connectnet.com>
Source record: 107532

Picked up an interesting item at the local "Industrial Liquidator's" yesterday, and I'm wondering if there's anyone out there who can help me learn to interface it.

It's a dot-matrix LCD display, 128x67 (I think, it's somewhere between 64 and 70). It has a board attached to the back that has three SMT ICs and one of those odd ribbon connectors like you find inside a PC keyboard, and also inside a lot of lap-tops. Two of the ICs are HD61202s, and one is an HD61203. The ribbon is twenty-conductor.

The board is silk-screened with the name "Solomon" and what looks to me like a part number "LM7310SGLU." The bin that the item was found in indicated that the display could 'do' grapics.

I'm planning on (eventually) using this item to display information either for my packet/satellite station (still in the conceptual stage), or for my HF station (also still in the conceptual stage).

Any help anyone out there can offer would be most welcome.

>These are 16 pin DIP VCO s.

Hi, Doug -

I just got an Oct-Dec 1995 Jameco catalogue that lists the MC1648P
for $3.95 in quantity 1-9. Mail is a little slow getting here.

They are at 800-831-4242 voice or 800-237-6948 FAX. I don't think they
have a minimum order, but they want $5 'processing' for orders under
$25. That'd be no problem for me - looking through that catalogue
at all the parts I can't get here, I can run up a $25 order in about
thirty seconds flat ;-). BTW, the Jameco catalogue shows it as a
14 pin DIP.

Hope this helps - 73

Ok, here's a repost of an SCA decoder. Before someone flames me
again for how complex the circuit is, 1) it isn't that complex, it
just looks that way because I dislike ASCII schematics and 2)
it receives all of the sca subcarriers from 62 to 95 Khz unlike one
based on a PLL with a fixed band pass circuit.

I recommend the Mc3361 as a replacement for the Mc3359 since the
Mc3361 has reached jellybean status and is available from three
suppliers (Motorola, Signetics, and Samsung). If you have enough
experience to build the circuit, you should be able to do the
substition using the suggested circuits in the Motorola (or Signetics
Linear - Communications) data books.

start of old posting ----

Here is a description of an SCA decoder using the Motorola Mc3359
Low Power Narrowband FM IF integrated circuit.

What is SCA

SCA or Subsidiary Communications Authorization is a method
of piggybacking signals on the normal audio programming from FM
Broadcast stations. Normally, the audio program occupies
the frequencies (after FM detection) from 0 to 15 Khz, there
is a 19 Khz pilot tone for stereo, then the Double Sideband
Supressed Carrier Stereo Difference signal takes 38 Khz +/- 15 Khz.
There is room above all that for other signals, using the range
60 to around 100 Khz. About the only limitation the FCC places
on the signal is how much the SCA signals modulate the main RF
carrier. Monophonic FM stations can use subcarriers in the range
of 20 to 100 Khz.

The usual audio signals are narrowband FM subcarriers with a
deviation of +/- 5 Khz. Common subcarrier frequencies are 67, 75, and
92 Khz.

There are also FSK and PSK data subcarriers for such uses as
stock market tickertapes and paging.

Content, Property Rights and ECPA

The signals can be used for whatever the station can
get money for. Talking newspapers for the blind, "Muzak", and
ethnic programming are signals I've monitored in my area.

These are not considered public broadcasts, and are covered
under some form of copyright or performance right. There is some
question that the Electronic Communications Privacy Act may disallow
listening to SCA signals. So don't try to go into competition with
the program providers, because they are the ones collecting the
subscription payments and the law is on their side.

Theory of Operation

The Mc3359 is one of several similar chips designed to
be the second IF for a narrowband FM receiver. It has a local
oscillator, a balanced mixer, a limiting IF amplifier, a FM
quadrature detector. Also included is an OP amp, and a squelch/
mute circuit which is not used. It is documented in Motorola's
Linear and Interface Integrated Circuits databook (DL128).
The specifications state that it produces a useful audio signal
with an input of around 10 microvolts. (Quite a change from
logic thresholds for this digital hacker.)

In this case, the signal is obtained from the output of the FM
detector inside a FM tuner. The input resistor (R1) is large to prevent
loading down the tuner's circuitry. Then a parallel LC tuned circuit
(C1,C2,L1) selects the desired subcarrier. The Local Osc. frequency
is set by L2, C4 and C5. This should be in the range of 388 (455 - 67)
Khz to 363 (455 - 92) Khz. The output of the mixer is filtered by a
three terminal ceramic bandpass filter, X1, (Not a ceramic resonater
used for oscillators). The limiter input (the output of the filter) is the
pin most senstive to spurious signal pickup. Keep that wire short.
The limiter output is processed through a quadrature detector, a balanced

mixer combined with a tuned circuit (L3 with an internal capacitor),
to produce the audio frequency signal, deemphasized and filtered by
R3, c11, c12, r4, etc.

Parts

First try the nearest Motorola distributor. I got the IC
at a local (Seattle area) retailer called Supertronix. (Sort of
a local "Radio Shack on Steroids" with a large selection
(206) 251-8484).
It's also in the NTE (and ECG) inventory as a NTE-860 ($$$ warning).
A Mc3357 is similar, but requires more external parts.

The inductors and bandpass filter are available from DIGI-KEY.
I haven't yet tried the Toko 154ANS-T1020Z for L2, should work. ;-)
The J. W. Miller 9001 is a big ugly wide range thing.

Adjustment

First, power the circuit up with no input signal, 4 to
9 volts, 3 mA. Hook the audio output up to your amplifer (about
.5 V signal). With a DC voltmeter or 'scope across C11, adjust L3
across it's range. At one end, the voltage should be about .5 V DC,
at the other end the voltage should be about 1 volt below the power
voltage. The transition should be abrupt. In the transition area,
adjust L3 so the voltage is halfway between the two extremes. This
should be the point for the loudest output of random noise.

If you have a frequency counter, scope, or LF receiver, look
at pin 2 and adjust L2 for the subcarrier you want to try first. 388
Khz is a good bet. With L3 adjusted, it really isn't that critical.

Hook the input to the FM detector output inside your FM receiver/tuner.
(You'll have to figure this out yourself), and tune to the station
with a SCA subcarrier. Quality of reception is important. If the
normal broadcast audio isn't clear, the subcarriers will be drown out
by noise and distortion. Tune L2, when a signal is there, you'll get
a quiet output, or hear the music.

Even with L1 misadjusted, the the chip is sensitive enough to pick the
subcarrier up. Adjust L1 for the lowest extraneous noise.
Alternatively, you can hook an audio oscillator to the input, instead of
the FM receiver, set to 67 (or whatever) Khz, .1 to .5 Volt, look at pin 18,
and tune L1 for a peak AC voltage.

Performance

There is still a lot of crud in the audio, but it's good enough to tell
you what's out there. (Most SCA signals use some sort of compression
to reduce noise, which this circuit doesn't do.)

I use a Canon Bj-10 to print transparencies. The "trick" is to print
two of them. Place one over the other, making very sure they match
exactly, and tape them together. This should help alleviate the
problem, unless you've got major size holes in the traces.

There are articles in the old Dutch Free Radio Magazine (Pirates off course). All based on "normal" components. I can post a copy to you, if you contact me.

Intead of buying costly temperature compensating capacitors, consider the circuit on page 14.20 of the 1996 ARRL Handbook, which uses a pair of thermistors to control a varactor diode.

Even better might be a digital circuit that can differentiate between warmup drift and temperature variation, as well as accomodate non-linearities easily. But, I've not seen a published example to copy.

911. Reducing IC-735 6-meter spurs

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-02 00:00:00 UTC
From: an142028@anon.penet.fi
Message-ID: <150341Z02021996@anon.penet.fi>
Source record: 107540

REDUCING 6-METER SPURS FROM THE ICOM IC-735

Recently, I assembled a Ten-Tec 1208 6-meter Transverter Kit which my XYL had given me for Christmas, and which I planned to use with my Icom IC-735 HF rig to return to 6 meters after a hiatus of about 15 years. The "Blizzard of '96" having rendered outdoor work unpalatable, and roof work downright dangerous because of snow and ice accumulation, I decided to build a simple dipole and install it in the attic. This done, I proceeded to give 6 meters a try - but what a cacophony of in-band spurs greeted my ears!

With the 1208 connected to the dipole, which is located in the attic and about eight feet directly above the shack, tuning across the band from 50.0 to 50.250 (14.0 to 14.250 on the IC-735) revealed a vast array of spurs - some fixed frequency, and some of which "stepped" as the IC-735 was tuned - ranging in amplitude from right at the noise level (about S-2 on the IC-735 S-meter) to S-8. Several of the most prominent in the primary range of interest between 50.025 and 50.225 are listed below:

Frequency (MHz) Amplitude Description
~~~~~~~~~~~~~~~ ~~~~~~~~~ ~~~~~~~~~~~
50.047 S-7 Steady carrier

50.100 S-8 Steady carrier

50.121 S-6 Step (follows
IC-735 tuning)
50.200 S-8 Mixed, steady &
step
50.226 S-6 Step

Although I was able to successfully use the IC-735/1208 combo with the indoor dipole for 16 QSOs in 5 grids during the January VHF Sweepstakes, the presence of such a multiplicity of spurs, at least some of which were apparently emanating from the IC-735 (witness the "step" signals noted in the table above), was deemed unsatisfactory. I therefore proceeded to investigate the nature of the problem and to attempt to determine a solution.

The first thing I noticed was that removing the microphone from the HF rig eliminated many of the spurs and drastically lowered the amplitude of the stronger ones.
~~~~~~~~~~~~~~~

Using a short length of wire as an "antenna," I alternately touched each pin in the chassis connector and discovered that although several pins were "hot" with the spurs, the worst offender was the PTT ground line. Touching a small bypass capacitor between the PTT ground pin and the chassis reduced the amplitude of the spurs several S units.

A word about where the spurs come from: Most are present inside the IC-735, at least some of them are synthesizer-related, and they are conducted between the PLL board and a small auxiliary board mounted behind the front panel adjacent to the mike connector. Signals are carried from this auxiliary board to the mike connector via a small, thin, plastic ribbon with parallel circuit traces on it; the end of this ribbon is soldered to the pins on the back of the mike connector (the ribbon has an eyelet pattern which matches the pin layout on the connector). Needless to say, any signal present on any trace is readily coupled to other traces, and with the microphone plugged in a ready-made "antenna" is available to radiate these spurious signals.

Despite the use of small RF chokes and some bypassing on the auxiliary board, the spurious signal levels audible in the 6-meter band when the antenna is located in the proximity of the IC-735 are quite prominent and annoying. Obviously, mounting the 6-meter antenna outside, high and in the clear and as far away from the IC-735 as practical, will reduce the spurious pickup. Some of the spurs were so strong, however, that I deemed it appropriate to try and reduce the amplitudes as much as possible; if reduced to the point of being a mild annoyance with the antenna only eight feet from the rig, I surmised, then using an outside antenna should render them inconsequential.

Unwilling to immediately make internal modifications, I reconnected the microphone and tried clamping a ferrite RFI choke onto the mike cable adjacent to the connector. The RFI choke consists if two 1" x 1/2" x 1/4" thick pieces of ferrite material, each with a longitudinal semicircular groove in it. Each piece is mounted in a hinged plastic cover and forms half of a clamp which, when placed over a cable and snapped shut, is supposed to reduce RFI leaving the equipment and traveling down the cable. It is intended to be used on personal computers to prevent radiation from keyboard and monitor cables.

The ferrite clamp proved to be something of a disappointment; while it did reduce the amplitude of the spurs, using one clamp only reduced the level about an S unit and using two reduced the level no more than half an S-unit more. Given the amplitude of some of the spurs, I considered

this to be inadequate, and so set about to determine what internal modifications could improve the situation.

I will spare the reader the details of all the measurements and combinations tried, but suffice it to say that internal bypassing is the only way to effectively reduce the spurs to a point where they become barely an annoyance; I was unable to eliminate them entirely. The remainder of this discussion deals with the final modifications as they were incorporated in my IC-735.

To accomplish the internal bypassing, first remove the top and bottom covers of the IC-735 and lay it on its top with the front panel facing to the left. This puts the mike connector on the observer's left and immediately in front. Behind the mike connector is a small, vertically-mounted circuit board, and pointing towards the observer from this board are several small, green RF chokes in approximate vertical alignment. These chokes are, from top to bottom: L8, L7, L6, L5, L4, and L3, and are in-line chokes for the PTT, squelch, UP/DOWN control, +8 vdc, audio output, and microphone "hot" lines, respectively. L2, the microphone return, is located on the same board but on the bottom left as viewed by the observer and is pretty inaccessible.

Since L7 (squelch), L5 (+8 vdc) and L4 (audio output) are not connected to any wires in the mike cable when the standard HM-12 hand mike is used, they can be ignored. This leaves L8 (PTT), L6 (UP/DOWN), and L3 (mike) which could be bypassed. During testing I determined that bypassing these chokes reduced the spur levels as follows (tests performed while monitoring the 50.100 spur):

L8 bypassed: Level reduced from S-7 to S-6
L6 bypassed: Level reduced from S-7 to S-4
L3 bypassed: Level reduced from S-7 to S-6

I also determined that bypassing L2 (mike return) would reduce the spur from S-7 to S-5, and bypassing pin 6 on the mike connector (PTT return, which does not pass through a choke) would reduce the level from S-7 to S-4. L-2 is located such that my soldering iron wouldn't reach it, but pin 6 of the mike connector was barely accessible from behind by *very carefully* reaching in. I therefore determined that I would install three bypass caps: One on pin 6 of the connector (PTT return), one on L8 (PTT), and one on L6 (UP/DOWN). Since bypassing L3 (mike) had only a minimal effect at best, it would be left alone.

The capacitors I chose were all CK05 square ceramic types, but disc ceramics should work just as well. The values I used were 0.1 ufd for bypassing pin 6 of the mike

connector and 0.01 ufd for bypassing L8 and L6.

The RF chokes are easily bypassed, since they are mounted vertically to the board (horizontally to the observer) with the outer-most lead looped back down to the board. Make a small "hook" in one lead of a bypass capacitor (cut the lead length to about 1/4" or so), hook it over the wire of the loop, and tack it with the soldering iron; the other lead of the bypass capacitor should be grounded. Alternate loops have insulating sleeving on them, but as it happens the loops of L8 and L6 (top and third from the top as viewed by an observer with the rig upside down as described) have no sleeving and so the connections are easily made (see the note below regarding the ground connection point).

Connecting to pin 6 of the mike connector is a bit trickier: First, make a small loop in one lead of a capacitor (the lead can be cut to about 3/8" long first), bend the loop 90 degrees, then slip it over the pin. Reach in *VERY* carefully with a small soldering iron (25 watts or less) and "tack" the lead to the pin. ***USE EXTREME CARE NOT TO TOUCH THE PLASTIC RIBBON OR ANY OTHER INTERNAL COMPONENTS OR WIRES!!!***

The free lead of each bypass capacitor should go to chassis ground, and this is easily accomplished by mounting a solder lug under the nearest PC board holddown screw on the large board mounted to the underside of the IC-735. This brass screw is plainly visible on the left front edge of the board (as viewed by the observer with the radio facing left); just remove the screw, lockwasher and flatwasher, slip a lug over the screw shaft, and reinstall the screw with the lug facing toward the rear of the front panel. I used one of the long, tapered lugs. It's easiest if you install the lug *FIRST* before installing any of the bypass caps.

After installing the three bypass capacitors most of the spurs had been reduced to the point of being completely inaudible. Of the strongest of the original spurs, the two at 50.100 and 50.200 are barely audible at the noise level, the synthesizer-derived "step" spurs at 50.121 and 50.225 are no more than S-3 (with an S-2 noise level and the IC-735 preamp turned on), and only the 50.047 steady carrier is unchanged at S-7 (my guess is that this is an external signal; I have a couple on 2 meters from the local TV cable). There are no other spurs of any consequence within the range from 50.100 to 50.225 -oh, perhaps a very faint, almost inaudible remnant in two or three places - but nothing to interfere with weak signal operation. An outside yagi should only make things better.

For those who may be wondering, I actually tried cutting the UP/DOWN line at L6 but it made almost no difference; bypassing is the only thing that really seems to work. Oh, yes, don't forget to ground the IC-735 to your station ground via the rear panel ground jack - the difference between "grounded" and "ungrounded" is about half an S unit (with no bypassing).

Incidentally, the modifications have had no adverse effect on operation of the IC-735, and in fact have made 6-meter operation very pleasurable. I can't wait for that first sporadic E band opening!

If you have questions or comments about the problem, tests, or procedures described, please feel free to drop me an e-mail at pbock@melpar.esys.com or call me at (703) 560-5000 x 2062 (weekdays) or (540) 882-4745 (evenings/weekends).

>anold 20W transmitter vac tube design.. and a corresponding reciever.

Wellcome.

However, when you want to build your own gear, it is vrey important
to carefully choose a design. there are of course lots of nice
designs around, eg in the ARRL Handbook. For simplicity and performance
designs with transistors and integrated circuits are best. Tubes are
only of interest once you get into the state when you are thinking about
a kilowatt output power on transmit.

What you want is the BA-1404. Everything you need is on one chip. Get the Ramsey FM-10 or DC Electronics Stereocaster kit for $30 or so.. By the time you find the BA-1404, a 38 KHz crystal, etc., you may as well have bought the kit. I got a Stereocaster and replaced the output transistor with a MRF581. It was good for 1/4 watt or so when run off 12 volts.. Don't forget a low pass filter...

Oh, and they don't use PLL's, but the Stereocaster was stable enough after running for 10 or 15 minutes. The Ramsey is said to drift a little more.

Check alt.pirate.radio (or alt.radio.pirate?)for a FAQ. There's a FTP site at ftp.dg.rtp.com or something like that, and a few web pages floating around.

I think a good compromise would be to put the software listing on the net somewhere and on a dial up BBS. Anyone who is going to do their own programming has got to have a PC and should be able to get a modem (even an old 1200/2400 baud!). If they subscribe and desire to do so they could download and print the software and keep it with the magazine. Anyone trying to build it after 3-5 years might have to recreate the software unless it made its way to some of the Ham CDs. The same could be done for board layouts using .pdf format. (Boy that'll start a flaming thread...)

I would characterize the article as "construction" as it had full schematics and circuit descriptions.

I would characterize it as useful because of what it contained. That does not mean it could not be more useful by including the parts that were omitted!

It was a more useful article than the antenna tuner (very personal opinion).

Here's what a local repeater club in So. Cal. did:

-Changed the status of their repeater from 'open' to 'private', so that only club members are 'supposed' to use it.

-Got a restraining order prohibiting the undesired user from using the repeater.

The restraining order was enforced & the undesired user was forced off the repeater, along with lots of 'good' non-member users.

>the resistors/caps is usually enough).

Admittedly, I've never evaluated one of these transmitter fingerprinting systems myself, but I have a little trouble believing some of the claims made about them. For example, the claim that each and every radio

is uniquely identifiable, even radios of the same model and production run. Granted, variation in component values will result in slightly different PLL characteristics, but I have yet to see any evidence that suggests that the resulting fingerprint varies enough to be considered "unique". Also, component ageing and temperature variation can cause considerable drift over time, and I haven't seen any evidence that this drift isn't great enough to change the "fingerprint" of the radio.

Another factor worth mentioning is that the characteristics of a PLL may change considerably as you change frequency, due to variation in gain of the VCO. A fingerprint taken at 144.0MHz may not "match" a fingerprint taken at 148.0MHz, for instance.

I'm also interested in how accurate the software algorithms are that are used to compare a captured fingerprint with stored fingerprints. I can't help but speculate these algorithms generate a likelihood of match measurement, and some arbritary level is used as a decision point (like, say 90% likelihood of match). Too loose a standard and many radios will match one fingerprint, too tight a standard and one radio won't match it's own fingerprint from one day to the next (or even one frequency to the next).

I've worked with people that built radar-signature analyzers (part of an electronic countermeasures system) and they indicated that the signature of a model of transmitter was very consistent from one unit to the next. Granted, radar transmitters are different than PLL controlled transmitters, primarily that a radar transmiter signature consists of both amplitude and frequency variation and a PLL transmitter signature is composed of frequency variation, but the fingerprinting technology depended on a high degree of consistency from one unit to the next.

Every time I bring this up, I get a handful of mail messages from people saying "we have it and we swear it works", and I think the concept is really neat and I'm sure there are some neat prototypes. I'm just not convinced the people using this technology are completely aware of how it works, and/or being completely honest about how well it works. I'm curious, and want to research it more sometime, and it would be neat if could discuss this technology objectively without immediately descending into an unrelated thread about repeaters, jammers, scumbags and the FCC.

Please note that I trimmed the Newsgroups: line, and have set the Followup-To: line to rec.radio.amateur.equipment.

I think last year was the 40th annivesary of WD-40. There
was a program on it on NPR (or something). It was the 40th
formulation tested to stop rocket parts (or jet aircraft
parts) from sticking together (or rusting, don't exactly
remember the whole story). WD-40 is the only product of
the WD-40 company. I don't think the guy who invented it
made much money out of it - it was formulated as an in-house
thing.

Controlled carrier AM has the same fidelity as any other AM system, they
are all limited by the skill of the designer.

The idea of controlled carrier AM is to reduce dissipation between words.
So it allows the PA to be used at it's PEP rating rather than it's
continious dissipation rating.

You have to be careful to increase the carrier *before* the modulation
increases, and decrease it *after* the modulation decreases. You can use
controlled carrier with control grid, screen, cathode, or plate
modulation. In my view, it's just one more thing to go wrong for the small
increase in power it provides.

For example, a 100 watt dissipation PA capable of 800 watts PEP can
operate at more than 200 watts carrier output in plate modulated class C
voice operation. That's because efficiency can be well over 70%. (RCA made
a plate modulated AM BCB transmirtter that had 90% plus carrier eff)

The same PA can only operate at 50 watts AM carrier output (200 watts PEP)
in linear or grid modulated service, because the efficiency is restricted
to 33% or less.

With controlled carrier, in theory each PA can operate at the maximum 800
PEP during modulation peaks of short duration with a long cooling off time
in between, but the real world result of normal modulation duty cycles
limit it to a figure more like 400 watts PEP (100 watts carrier). So you
gain 3 dB for a *LOT* of grief in adjustments.

A better solution is to reduce the carrier. The weak carrier can be
filtered and amplified in the receiver and re-injected with the audio
sidebands. Or another carrier can be generated and re-injected in the
receiver. This modulation scheme also can be arranged to remove signal
from one sideband and add it to the other, allowing narrower receiver BW
and improved S/N ratios.You can do this easily in the PA by adding phase
shift to the carrier and audio signals, or by a modulator/filter scheme.

I use this system all the time. If you tune around, you will find other experimenters using it.

As I recall, Collins mechanical filters are 455 KHz. Toyo makes inexpensive 455 KHz ceramic resonators and filters in various bandwidths, and DigiKey sells them. Obviously these are no match for the mechanical filters. However they are cheap enough such that you could cascade them or use them in various feedback configurations. I saw one design where the ceramic resonator was used instead of an emitter bypass capacitor in an IF amp. The low cost and easy availability of these filters invite experimentation.

>want. I've seen the chip sold separatly but can't find a listing in a catalog
>just for the chip at the present time.

I know of one single-chip FM stereo transmitter. That's the BA1404. Add
a 38 kHz crystal and a handful of resistors and capacitors, and you have
a transmitter that runs on 1.5 to 3V. Sorry, I don't remember who manufactures
the chip.

DC Electronics sells these chips (~$2), as well as a kit (~$20). I built this
kit and it worked fine for my purposes - transmitting from a CD player to
a nearby FM radio.

I've heard that this kit may drift too much to work well on the newer
digitally-tuned receivers. Older receivers used a PLL to lock onto the
signal, so they receive just fine.

I'm not sure if Ramsey uses this chip in their transmitters. At least one of
the Ramsey kits advertises "Synthesized 88 to 108 MHz." Presumably
this transmitter would work well with digitally-tuned receivers.

Hi:
I use to only use two radios. One SW receiver, and an ordinary AM is fine. Find the SSB on the SW receiver, and tune around with the AM radio (with the volume down) until you hear a hetrodyning from the AM radio. A simple AM radio can transmit a strong signal sometimes! more than likely, you will be able to find a spur in the band your listening.

Sure!

Standard Group III fax at each end of a HF radio link. Fully automatic operation at both ends.

Codan Pty. Ltd. (my employer) produces such a system. It is of course a store-and-forward system and you can send a typical fax in less than 5 minutes.

Now I know how sensitive Internetters are to commercials, so if you want more info, email me on rsilva@adelaide.dialix.oz.au . If you ask nicely, I'll even tell you about the competitor's products :-)

See Weak Signals with your PC & Soundcard

FFTDSP is a PC program which uses the soundcard
and audio from your radio to detect weak signals

The original FFTDSP38 program displays a
screen (spectrograph) which shows weak
signals as color traces against a dark background.
A continuous 4096 Point FFT (fast Fourier transform)
is used to provide 640, 2Hz wide filters.

FFTDSP41 - Beta Demo Version now available

Key Additional Features of the upgraded FFTDSP are:

- Record and Playback WAV files for post spectral analysis
- Automatic Color Gradient for optimum visibility
- Integration mode for signal detection below the noise
- Mouse point and click for selective recording
- On screen Moon position and TOD tracking
- True S/N (in 100 Hz Ref) bar graph
- Selective area and mode for S/N display
- Display Smoothing Filters
- Zoom In/Out for wider frequency coverage
- Improved Graphics Interface and Setup Screens
- Find Call feature from partial information

Available Download Sites for Beta Demo:

945. QRP Schematics scanned and ready!

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-03 00:00:00 UTC
From: kmiller@airmail.net
Message-ID: <4f0sru$as8@news-f.iadfw.net>
Source record: 107563

Hi guys, I finally got the schematics scanned today. They need a little cleaning up, but they're about ready. I'm open for suggestions, should I post them here, somewhere else, or just e-mail them to whoever wants them. Does anybody mind if I post them here? Is there a proper place to post a schematic? They are bmp's now, would .jpg's be better?

All these dumb questions from a newbie poster! I don't even know for sure I can post them, but I'll try it somewhere first.
Thanks,
Kerry Miller

>any replies commenting on how much you hate am will be ignored.

Not sure about the audio response, but know about controlled carrier
a.m. a little. I hv an old set of Drake Twins which use controlled
carrier. The guys on the other end don't seem to even notice the
difference unless I say something about it. The benefit isn't so much
that you get more power, but that you have less dissipation to get the
same power. The Drake uses sweep tubes, it wouldn't do but a few
watts if it used regular full carrier a.m. Sounds like a neat
project, good luck!

Ok, so I didn't provide any help, just defending a.m. in advance of
the attacks! I also run a Yaesu FT-990, but the a.m. sounds better on
the Drakes, even though it has less power!
73,
Kerry

Thomas G. McWilliams (tgm@netcom.com) wrote:
: Mark Mansfield (markman@UTM.Edu) wrote:
: : I'm looking for a pair of Collins (or equiv.) mechanical filters for a
: : CW receiver which I'm building. I'm planning on using one of the filters
: : in the front of the IF and using another in the "tail-ended" mode after

: As I recall, Collins mechanical filters are 455 KHz.

Collins mech filters are available in a number of center freqs.
My junkbox has CF's of 455, 450, 462, 500, 250 kHz, and maybe
others.

<Shameless Plug> e-mail for a list of filters for sale.

: Toyo makes
: inexpensive 455 KHz ceramic resonators and filters in various
: bandwidths, and DigiKey sells them. Obviously these are no match for
: the mechanical filters. However they are cheap enough such that you
: could cascade them or use them in various feedback configurations. I
: saw one design where the ceramic resonator was used instead of an
: emitter bypass capacitor in an IF amp. The low cost and easy
: availability of these filters invite experimentation.

Note: ceramic resonators are a two terminal device, much like
a quartz crystal, except not as stable or as high a Q.

Replacing the emitter bypass cap of the IF stages DOES work well,
but is becoming less of an available option as receivers go to
mostly integrated circuits. You have some degree of control over
the results by selecting the resonators: two resonators with a
CF of 455 kHz will give a sharper IF than one of 456 and one
of 454 kHz.

This has been an interesting thread, but perhaps it should stay
in r.r.a.homebrew, and not rec.radio.swap if continued.

949. Re: PTO Temperature Compensation

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-04 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <823443771.29689@pinetree.microserve.com>
Source record: 107474

First, I want to thank everyone for the excellent ideas and information on this subject.

The first two PTO's are back in the rig now and I have had a chance to use them on the air for a few days. They seem to have settled down a little, or at least they're not showing the same drift characteristics as when they were on the test bench. I'm not sure why that is, because I was testing them in the rig after each change.

At any rate, the initial, slow warmup drift now seems to be downward rather than upward, indicating that some additional compensation might be needed. It's not too bad though, and I may leave it as-is. The drift that occurs when I begin transmitting (which is aggravated when I use my amplifier because it's next to the rig), is still in an upward direction.

This may be the result of a temperature gradient across the PTO components (I think it was Cliff who mentioned that possibility). Short of potting the PTO or installing a heater, there may not be much I can do about this. I want to mention that the problem isn't all that bad, and maybe I'm just being picky. I was reading an older receiver construction article recently titled "An Engineer's Ham-Band Receiver", which describes a very well-constructed piece of equipment. The author's VFO was built on a custom (heavy) subassembly using a few of the parts from a BC-221 frequency meter. When he talks about how good the stability is, he describes it as being within 5 ppm per degree (Centigrade, I think). Now, if my math is correct, that means that at a PTO frequency of approximately 5 MHz, a temperature change from 70F to 80F could cause a frequency change of as much as 150 Hz. Actually, the PTO's I've already worked on are not be too far from that kind of stability at this point, at least for initial drift.

I guess what's bothering me most about this is that my old Yaesu FT-101EE was like a rock, despite the fact it was a hybrid. After a fifteen minute warmup, I could ragchew for hours on CW without touching the dial once. Maybe this was just luck of the draw; some owners I've talked to have apparently had major problems with drift in their 101's.

Anyway, the responses to my original question are enough to keep me busy reading, checking components and experimenting for several weeks or even months. As a possible alternative before I start this project in earnest, can anyone tell me whether it's feasible to consider replacing the PTO's with 5-5.5 MHz synthesizers? I've missed most of the QST/CQ/Ham Radio articles in the last five years so I'm not familiar with advances regarding available components. Is it possible to build a synthesizer for this application with 10 Hz resolution at a reasonable

cost, say with two or three chips? Or is this the type of design that still requires a fairly complex circuit?

Tnx & 73,
Jack WB3U

I built one a couple of years ago. It worked well and heard plenty signals with about 20 feet of wire.
It took only an evening and the manual was easy to follow. It describes the function of the components as you put them in so its a good learning experience.
I just sent the 40 meter receiver kit as a gift for my nephew so he can pick up W1AW from Phila.
The tuning with the single variable resistor is too broad. Put in the bandspread one suggested in the manual.

Check your DigiKey catalog. They're nominal 130 VAC "ZNR"s. 4500
Amp surge rating. They'd make ideal surge suppressors for 120 Volt AC
applications like turning a regular outlet strip into a "protected" strip.

Buy an Ameritron AL-80B bandswitch and use the wafers in the Heathkit. The single rear wafer is the only one necessary to use, unless you want 160 through 10.

The voltage rating is higher, so the switch won't be damaged as easily if you mis-tune or underload the amp.. Improper loading is by far the biggest cause of switch failure.

<triangle symbol>ZNR
14K201U
<backwards R>U 46

It's black, shiny, looks like a disc cap but is a bit too thick to be one of those, and I can see through the coating that the leads bend and go to the center of the material. I'd like to find out what the joule rating is for these - maybe they'd be useful. I got a bunch of them in a Circuit Specialists mystery box. My meter says the capacitance is 878 pF.

Most diodes will exhibit Varactor charicteristics when biased properly. The ones that are solely
for Varactor usage are just doped differently vs. detector/rectifier types.

BTW, any sources for those units mentioned in your previous post???

Your drift now may be due to rf heating.
Commercial VFOs use multiple caps in parallel in areas of RF in the
VFO.
This is addressed in the ARRL handbook.
The theory is the RF will distrubute itself across the parallel
caps and reduce the capacitance change due to heating, The heating
is caused by dielectric loss and RF.

Maybe you can get the thing totally settled dowm.

The ZNR implies that they are made by Panasonic.
Digi-Key sells Panasonic MOVs.
Their catalog should shead some light on the ratings.

201 gives voltage at 200 volts +- 10%
14 is the series surge current is 4500 Amps.
Max allowable voltage ia 130 VAC, 270 VDC

Hope this helps

I have heard a rumor that HP/Avantek is getting out of the VCO business.
You may want to try other sources such as Magnum Microwave and
WAtkins-Johnson. HP does have a number of Web sites that you can do a
Yahoo search to find.

Good luck-
Larry

I am looking for info concerning the fromat of the remote control
data stream used by the Yaesu MH-29(a2b) speaker mic and the FT-530 dual
band
HT. I do not have the aforementioned speaker mic, so I can't "reverse
engineer"
the spec. I want to build a remote control interface for my computer and
need the formats to change frequency, band, etc...

I have been trying to do the same with my KODAK lazer printer.
Generally it is black enough now I have set it darker from the slider
bar in printer setup options in windows 3.1. although the acetate film
I am using goes a bit crinckly through the heated rollers.
Have you any suggestions as to software for making PCB layouts?

Check out those transformers before you start. I don't know much about
them but if you look at the iron core you will see a magnetic shunt
between the primary and secondary. Make sure they will do the job
for you before you go too far.

Controlled carrier AM is a lot harder to get to work *right* than
it may appear. It's usually better to just beef up the PA to run
regular plate modulation, or build a high level DSB rig. The latter
is even more conserving of input power, and not really harder to
do than doing controlled carrier correctly.

Ok, here goes nothing. I'm trying a small one first. This is a single-chip vfo/exciter from 73 magazine. It has several files, all zipped together into 1. The parts list may not be legible, so I retyped it along with some instructions for the tuning capacitor. If this one works, I'll start sending the others as soon as I get them cleaned up a little better.

I've heard from several guys, if email attatchments work better, I'll do that too, I'm easy! I'll give this a try, be patient, I've never posted a file before. Funny, you get DXCC, but you still don't know how to use a stupid news reader! Here goes nothing, hope it works!

Let me know what you think. The other ones are a 40 and an 80 meter transmitter, and a few odd tx/rx/tranceiver schematics. I'll attatch the schematic to a different file so those who aren't interested won't have to wait on a download!

Seems I've read on one of the newsgroups a while back of modifying a cell phone into a transceiver. I picked up a couple of Motorola cell phones for next to nothing at a "junk" store the other day thinking they were transceivers (the handset was missing so I didn't know exactly what they were <g>).

Anyone know if this is possible? And how do you go about it?

Thanks for any help you can give me!

>Tnx & 73,
>Jack WB3U

As a synthesizer designer, I'd say to be careful. I really think it's so much easier to design a bad synthesizer than a bad PTO, that I wouldn't recommend going that route. Unless you want to read up on and learn about PLL design as a new hobby, in which case go for it.

That said, I think I'd look long and hard at a DDS for this job. Use a TCXO for the source, and get one of those CMOS DDSes that will handle at least a 20 MHz clock. Wrap a good tight BP filter around it, and it seems like a good approach.

Any reasonable approach using regular PLLs would entail at least a couple of loops, and be fairly complex, IMO.

981. Re: wrinkle paint

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-05 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <823526669.21059@pinetree.microserve.com>
Source record: 107499

This is slightly off the subject, but I wanted to mention something that might help someone who's painting a cabinet but doesn't want wrinkle paint.

I recently built a custom desk for my ham shack and I needed to match a light gray formica finish on some other office furniture in the same room (as per instructions from XYL). The paint I used was Dutch Boy Floor and Porch polyurethane enamel, custom mixed to match the color.

I brushed on two coats but the paint was very thick and it refused to completely level (even though it took six or seven hours for the surface to dry). What I ended up with was a lot of brush marks and streaks on an otherwise nice-looking desk.

Another application method was needed, but due to winter weather, it was impossible to load up my spray gun and take the piece outside. Finally, I went back to the hardware store and purchased several mini-size 3" paint rollers intended for trim work. I used these to apply a third coat to the piece, and that coat not only hid the previous faux pas, it left a great-looking textured finish.

I have since tried this paint on a small aluminum panel, using the same application technique but sanding the panel with 100-grit first. The result was a terrific semi-gloss finish with a *light* texture that looks like an expensive powder-coat paint job. After a week or so, the surface becomes so hard it's almost impossible to scratch unless you're really trying to damage it.

Anyone wanting to paint or repaint a piece of equipment owes this method a try. The materials are cheap and the resulting finish is tougher than many spray enamels (and much tougher than lacquer). Clean-up is simple too - throw away the roller and put the lid back on the can. This is one of the few ways I know to produce a genuine high-quality finish at home without commercial-grade equipment. With just a little care, it should last the life of the equipment.

Hello KC5RBM,

Use a web crawler to search for the info you need. A really good
search engine that I have found is run by DEC and is called
SuperSpider, at URL:

http://altavista.digital.com

I would suggest that you use the keywords "HTML" AND " Web Page",

Try the above string. There are so many sources that it is difficult
to list them.

A very good book can be had at BookStar book stores for
around $25, "HTML Publishing on the Internet", by Heslop & Budnick,
and is published by Vantena Press.

ISBN1-56604-229-1.

In addition to learning to write in HTML which is the language of
web page/home page construction, you might also consider CGI
and later Perl.

Good luck,

73's

I'm about to complete a small transmitter and need something to use
as
>a dummy load...

A #47 pilot lamp bulb works fairly well. On most SeaLand ships, the HF RF is passed through a couple of 100 watt household bulbs which offer lightening protection. It is crude, but it works well. Of course, at 2 watts, a 52 ohm resistor will work well. In fact, it will work up to about 5 watts intermittant duty as long as it's carbon as most 2 watts and less are. You could also parallel several larger resistors and get away with it. At HF and even lower VHF frequencies, it is not too critical. Radio shack sells a dummy load of about 15 or 20 watts, but that costs about $20.00 and really isn't necessary.

Well the catalog from my file does not show any Thordarson part # begining with a single letter "T". I also checked a Traid cross reference for Thordarson part # and no "T" either. I found a Thordarson 26R21 in thier catalog. It's a 350v CT at 225 Mils with 5v at 3 amps 6.3 at 10 amp and 6.3 at 2.7 amps. Size is 4.75H X 3.75W X 4.5" , Weight is 11.5 lb. The Thordarson catalog I have is OLD. It list thier phone number as 1200 in Mt. Carmel Illinois. That right only 4 digits. If the Xformer above is not close to the size you have give me some specks, and I'll see if I can find a match. 73 Tom

A few 2 W (or 1 W) carbon composition resistors in parallel (say two 100 ohms, 2 W) will fix you up. Use short leads and don't expect perfection at 144 MHz, but it will be adequate for most transmitter testing. Ask your friends to look in their junk boxes. These resistors are now a couple of dollars each, with a minimum order of 25 from Newark.

I'm seeing conflicting information on the technical specifications (i.e., temperature coefficient) of NP0 and C0G capacitors. Some sources indicate they're identical; others show slight percentage differences between the two. Is there a formal EIA specification for these two types?

Jordan's "Reference Data for Engineers," seventh edition lists ceramic capacitors in their respective EIA classes but not in terms of a three digit designator.

[long contorted story deleted]

Jack, it seems you have to isolate the PTOs from any source of changing heat, like your transmitting temperature change. This may be an additional approach to your transmitting problem.

Back to your effort to make the PTO temperature proof... maybe you should make every cap (including feedback caps) an NP0/C0G -- and check them for low drift by holding a soldering iron near them while listening! After withdrawing the iron (its mere proximity, hot or not, will of course move the frequency), see which way the heat moved it as you hear it settle back.

The more elements you have going in different directions at different rates, the more complicated it is :-). So eliminate as many of them as you can.

Then let it cool real good (hours), and make your from-cold-start drift evaluation, and temperature sensitivity evaluation... Then experiment with only ONE capacitance leg for the proper compensation.

Is there a varactor diode in there for offset tuning? Remember that this has a POSITIVE TEMP COEFFICIENT OF CAPACITANCE -- that is, increasing cap. with temperature, thus a freq. drift down, all other things being equal. You can get Motorola bulletin AN551 for detailed info on compensating this aspect, if present -- faxback service at <http://motserv.indirect.com/>

> after my results with the NPO's.

Test those NP0's, like I said -- not all are created equal, unless you have precise specs from a reliable manufacturer. Even then a little heat check wouldn't hurt in the operating circuit :-). And if you really need a + tempco, well, find a silver mica or whatever in your junk box that drifts in the right direction! Again, test with your trusty iron... why pay more?!

Just a few random thoughts... And what PTO's are you talking about?

Message-ID: <4f87so$bd8@newsgate.sps.mot.com>
Source record: 107435

The simplest QRP dummy load uses a 2-watt carbon resistor soldered
inside a PL-259. Drill a hole in a penny and solder the penny
to the connector and to the resistor lead.

It's best to use a 51-ohm resistor but a 47-ohm will work fine.
You should have the PL 259 and the resistor in your junk box.
(You math-heads, go figure the SWR and the impedance bump.)

These dummy loads work well past VHF frequencies and handle 2 watts
at 100% duty cycle, with a peak well above that. I never burned one
out when modifying CBs for 10 meters.

A 1-watt or 1/2-watt resistor may work, but it's not recommended
for power > 0.5 watts. Max operating frequency is lower, too.

Old-timers will recall that a light bulb works for a test load
and can give a relative power indication -- these radiate RF and do not
provide a matched load, but they will work if it's all you've got.

OK, everybody flame me now. N6OTQ

Hi David...

> does anyone have any 7910 or 7911 modem chips for sale. Either the AMD or
> SGS Thompson variety?

I have one brand new AM 7911 DC chip which I would willingly donate to help a good cause. If you consider that you are one <G>, then send me a stamped addressed envelope (see my web site) and I will send it back by return post.

BTW, I also have a built-up modem from a Wireless World design which uses, I think, a 7910 chip. It is built on their approved PCB and cased with a 240v PSU. It worked when I last used it some years ago. If that is of any interest I am open to offers.

1010. Re: PTO Temperature Compensation

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-06 00:00:00 UTC
From: rst@tetrault.com
Message-ID: <rst-0602960633290001@squaw-d118.sierra.net>
Source record: 107516

A crystal based digital frequency source may be possible with some increase in elaboration over one or two chips, and the result could well be more stable than the PTO, however the digital noise (and phase noise) of the modification will probably (almost certainly) be a step backwards, and there may be also a new host of idiosyncratic components to characterize in ways you never thought possible.

Good Luck.
Bob T.

1011. SB220 HELP NEEDED

>Bob NO6B

Bob,

That is a little extreme, although a popular route to take in some coastal states like CA and NY. I can not tell you how annoying it is to travel to California and find so many closed repeaters and closed autopatches. I, for one, would not continue to support the Arizona Repeater Association, if they closed their repeaters or autopatches.

The ARA has about 1100 dues paying members, and all our repeaters and FIVE autopatches in central Arizona are open to ALL licensed amateurs. Please feel free to use them when you are visiting Phoenix. BTW it's gonna be 80 degrees and sunny here today! I hope all you people in the rest of the US are enjoying your snow and record cold temperatures!

Also, please feel free to use the ThunderBird ARC repeater when in NW Phoenix on 145.43 (-) (no pl). :) We need a better antenna, so it's range is limited, for now. For those of you who are familiar with the area, this repeater is located on Phoenix General Hospital, I-17 and Beardsley Rd.

1015. Homebrew 160 Meter Vertical

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-06 00:00:00 UTC
From: ham@msg.ti.com
Message-ID: <ham.48.0121B620@msg.ti.com>
Source record: 107521
Cross-posted to: ti.rec.radio,rec.radio.amateur.antenna,rec.radio.amateur.homebrew

To anyone interested in homebrew antennae:

The following is an excerpt from EMail I sent to some K5OJI club (Texas Instruments ARC, Dallas) members interested in planning, modeling, and building a balloon-lifted vertical wire antenna for 160 Meters. This is to become a proposed antenna design specification for an antenna to be hoisted for Field Day '96. We welcome any hints, kinks, and suggestions for improvements in design, cost reduction, and payload minimization.
****
(on 5 Feb 1996, at 23:26z, Bil Morrison modulates:)

While at Texas Towers Monday, I invested in the ARRL's "Vertical Antenna Classics"book. I am taking some of the basic formulas and interpolating as necessary. Here is what I have computed:

Assuming what we want is a top loaded vertical, operating at 1/4 wavelength or 90 electrical degrees (we will use electrical degrees in order to use the LC constants nomigraph included in this book). The practical physical limit for top loading is considered as approx. 30 electrical degrees when applied to a disk (capacity hat). [ref: Laport, Radio Antenna Engineering, McGraw-Hill, Inc., 1952, p. 80].

In order to determinethe physical length of this theoretical antenna that uses the full limit of top loading, subtract 90 from 30. I then convert the resulting 60 degrees to feet by using this equation:

Lenth (in feet) = 2.73 X L (L = length in degrees)

---
f
MHz
= 91 ft

[ref: Dept. of Navy: Naval Shore Electronics Criteria: HF Radio Antenna Systems, Naval Electronics Systems Command, Washington, DC]

Okay, that's the easy part. Next step is to figure in the diameter of the 'mast'. In our case, I will chose an arbitrary value of 0.05 inches for #12 guage stranded wire, which is probably presumptuous. I will recalculate as necessary. What we need to do now is compute the 'conjugate impedance and 30 degree top-loading dimensions for an open-ended transmission line' <pant-pant>. Here is the equation [ref: Jasik, Antenna Engineering Handbook, McGraw-Hill, Inc., 1961, p. 19-3]:

Zo = 60 ([ln (2h) - 1] / a)

where ln = natural log (2.3
times common log),
h = height of vertical
'mast' in inches = 1092
a = radius of 'mast' in
inches = 0.05

= 581 ohms characteristic impedance

The 'Classics' book refers to a set of 'universal reactance curves' for open and shorted transmission lines. Where the 30 degree mark hits the open line curve, the value is 1.7, and is referred to as X / Zo. Since we have already calculated Zo as 581, multiply that times 1.7, and the result is 988 ohms reactance for 30 degrees top loading. All theoretical, of course <grin>.

Next, we must find our hat size. Here is where the LC constants and the nomigraph come into play. We place our ruler on the 1.8 MHz mark, and the other line to intersect at approx. 988 ohms, we find a crossing at about the 92 pf capacitance line.

The 'Classics' book also refers to the diameters of spheres, disks, and cylinders as a linear set of lines. Their sample of the graph would not go out to any further than a 60 inch disk. To get a capacity hat of 92 pf, we would need about a 105 inch, or 8.75 ft diameter hat. That's no Easter bonnet!! At this point, I must presume we would need some awsome fiberglass rods to make this work. Might I suggest REI as a source?
Maybe I will *loan* my tent poles for this grand experiment <g>.

The book goes on to describe a practical application, whereupon a six-sided wagon-wheel design was used, with the spokes terminated with #14 copper wire, which 'will increase the capacitance slightly'. Hope so, 'cause we can only launch so many pounds.

Now we get into ground radials. I don't even want to begin the calculations for this unless I assum a nominal design using 4 x .25 wavelength radials at 130 ft. ea. My guess is that we can come up with enough wire to set out 12 to 16. There is a whole chapter in the 'Classics' book regarding radials, so that will have to be another memo. From what I can tell, we'd be doing great at Field Day if we could put out 48 radials, which is optimum for 'poor' ground conditions. That means we could get 6 people to lay down 8 radials each. Good luck!

Back to conjugate impedance. We must now refer to the radiation resistance vs. antenna height in degrees curve [ref: ARRL, Vertical Antenna Cassics, p. 9]. For 90 degrees, we get 36 ohms radiation resistance. Here is where 'Classics' estimates a radial ground system loss resistance of 4 ohms for 60 radials, each .2 wavelengths long, for a total resistive value of 40 ohms. Boy, aren't we presumptuous today?

Back at the universal reactance curve, 90 electrical degrees yields a reactance value of zero. Therefore, the feedpoint impedance is:

Z = 40 plus/minus j0 ohms

I *think* this means we have a pretty close match using 52 ohm RG-213.
Going back to the radial system, we will try & understand what a 14 foot
piece of welded-wire fence lying down in the dirt will do to our ground system
(14' x 4').... someother time.

Here are the burning questions for the day. How many pounds will a 12' x 8'
surplus wx balloon, inflated with two full-size tanks (approx. 240 CF/tank)
of helium, carry to a height of about 100 feet into the air? We are presuming
at this point that fishing line would be used to tether the balloon in place
in order to maintain constant tangency above ground.

We want to determine how heavy guage wire can be used for the vertical. For
that matter, if we hoist the entire 90 degree electrical length, I assume it
will eliminate the need for a capacity hat.

> this the type of design that still requires a fairly complex
> circuit?

PLLs can be a can of worms in an application like this, but modern DDSs work well and are reasonably cheap. I'm currently experimenting with a DDS VFO based on a Qualcomm Q2220 DDS chip, which tunes in 3.7 Hz steps (55 MHz clock, 24 bit phase accumulator). It lends itself well to experimental playing around, since the programming inputs are parallel - you can even program it with DIP switches if you want!

The DDS article was in 73 a while back (Techno Whizzy - Dec '92?), while the microcontroller stuff is a custom TTL interface, a Basic Stamp microcontroller, an LCD display and a shaft encoder.

See also Technical Topics in the February 1996 issue of RadComm - there is discussion of combining DDSs and PLLs to make a VFO that combines the best of both worlds. If you don't want to go that route, tight filtering will still give good results over a smallish frequency range.

How about sweeping the DDS over the frequency range of interest, and if any particular frequencies show really nasty spurii, disallow them in the microcontroller?

Be prepared for significant power consumption (mine draws 190 mA), and be prepared to shield the thing well. Use *lots* of bypassing: I found that 1206 and 0805 chip capacitors are exactly the right size to nestle down in between PC board traces. You can get a PC board for the DDS from FAR; my microcontroller/interface board is currently a wire-wrapped rats nest.

The Analog Devices DDS chips (e.g. AD7008) are also handy, but are more expensive than the Qualcomm chip. They are serially programmable and have both sine and cosine ROM, both of which could be very useful.

According to Thordarson catalogue #400CX (Spring/Summer 1939), this transformer is a metal cased, general purpose power transformer:

Primary VA - 150

Secondary - 800 VAC CT @ 150 ma
5 VAC @5A
6.3 VAC CT @ 5A

Dimensions - 4 1/4W x 3 3/4D x 4 7/8H

Weight - 9 lbs

Hope this is of help.

Sir (name not given),

Avantek is the correct name. They have since sold out to Hewlett-Packard,
and given up the VCO business. I've used the Avantek VCO's for 3.5 GHz,
and they're really nice and linear. Sigh.
Oh, well, there are other sources.

The engineering company I work for uses such VCO's, and here are a couple
places we get them:

Z-COMM
9939 Via Parar
San Diego, CA 92126
(619) 621-2700

Mini-Circuits
Div. of Scientific Components
P.O. Box 350166
Brooklyn, NY 11235-0003
(718) 934-4500

I'm not sure what freq range you're looking for, but both of these
companies provide high-quality linear VCO's from about 150 MHz to at least
3.5 GHz. I personally have used the Z-COMM parts for 1296 MHz weak-signal
work, and they're relatively cheap ($10-$24 as of about 1 year ago).

The Z-COMM folks were really friendly and willing to sell me only one
VCO (which some places like Mini-Circuits won't do). Call them for
a catalog.

Mini-Circuits has stuff to 1240 MHz, for less than $20. Best of luck!

73,

Steve Bragg, KA9MVA

Steve,

Z-Communications in USA will sell you a single piece part. I personally have built a 1296-MHz synthesizer around their VCO, and they are quite linear and predictable. Z-COMM has VCO's to at least 2.4 GHz, and they are in the US$10 to US$25 price range (13.40 to 33.50 Aussie $, 1992 exchange; sorry, it's the most current rate I have). Write or call them at:

Z-Communications
9939 Via Pasar
San Diego, CA 92126 USA
USA TEL (619) 621-2722

Best of luck, and let me know how it comes out.

Hi All,

Everything thing Jim says is true, but I want to add a little bit. We had a big discussion about this a few months ago.

True non-inductive carbon and metal resistors are very rare, and the one and two waatters can be very reactive at VHF and UHF. Our plant goes directly to Allen-Bradley for them and pays about $.30 each for non-inductive carbon comps in 5000 lots.

Just because the resistor is carbon or metal based (rather than wire wound) it does not mean it's "non-inductive". As a matter of fact, even if the resistor specs say "non-inductive" it may not be suitable for some RF applications. Non-inductive is a very nebulous term.

Cut a sample resistor open and examine the insides (or measure it on a good analyzer). If it uses a ceramic core with a metal or carbon spiral for the resistance element....it is inductive. If it is made that way (and nearly off shelf units are) it may be ok for a load, or it may not. It will likey be very poor in a critical load like a parasitic supressor.

I've used the stuff from Meadowlake Corp, and it works OK.
You just have to be careful to apply the "right" amount of
heat and pressure.

One end of the spectrum is an incomplete xfer, the other is
"spreading" of the artwork.

1025. Re: Schematics going to a web page

Newsgroup: rec.radio.amateur.homebrew

Source record: 107443

Hi Kerry, there has been a lot of talk about posting schematics on the net. Some of the talk has been how (what format) some has been a lot of bandwidth of the legalities. I'm more interested in the how. In my mind a schematic should be in a machine readably format that can be "used". So not in GIF, TIFF etc type "Paint" formats. Sure you get the info from one place to another but if you send me a GIF file of a really neat QRP rig that I want to build I start by reentering it from scratch. Thus I term all paint type files as Engineering Napkins. You know, like in the old days when the CAD operator was a draftsman and the engineer was not involved in that stage. A better approach is to use some electronic format that includes the parts, connections and can create a netlist. One other desired feature is ASCII format so we can send it back and forth without UUEncoding etc. My (highly Jaded) view is to use CIRCAD. It meets all of the above and the program also works with OrCAD, Tango, Protel, ACAD and other files. The demo is free so everyone can view files. The demo also lets you write (aprox 32K) files so we can all exchange small files cheaply. So, thats my 2 cents worth. Thanks for the new WEB Site!

I'm not sure but I'm pretty sure that this type of display works a lot like
a TTY unit. Simple ASCII in (with some command handshaking) and you get
text. Everyone everywhere appears to use the same chipset which is
(I tink) the same ones you mentioned. I've written some assembler programs
to drive them from a printer port. The printer port works on except in the
4 bit mode (for unknown reasons) but it lets you try things out. Note that
the Doc for these things is awful hard to digest. Working code is worth it
weight in gold so when you get depressed E-Mail me or better yet send a SASE
and I will slip you a disk. Oh better yet send the disk!

Check the ARRL handbooks from the late 80s to possibly the early 90s. There is a VOX circuit in there using LM3900 current feedback op amps. I've built it and it works O.K. There is an error in the schematic regarding the 555 timer that is used. The schematic shorts out part of the 555 timer. The effect of this is to distroy part of the 555 timer. However, if the short is removed (I bent the offending pin up) the 555 timer will still do the job. If you check the 555 timer data sheet the error in the schematic will hopefully become obvious.

1034. Anyone else read Bowick's RF circuit Design?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-07 00:00:00 UTC
From: Ference Kish <fkish@attila.mtx.net.net>
Message-ID: <NEWTNews.823681677.16889.fkish@attila.mtx.net.au>
Source record: 107452

Hi!

I've just started reading Chris Bowick's RF Circuit Design.

I quite like it and recommend it to others, however, there is something that is puzzling me.

On pages 34 and 35 the book discusses the loaded Q of a resonant circuit; explains the effect of the source and load resistance on the Q of the tuned circuit.

Where I got a bit confused is Eq 2-6 onward. Bowick says that the Q of the circuit is

Q = Rp /Xp

where Rp is (Rs * Rl) / (Rs + Rl) and Xp is the inductive/capacitive reactance, Rs and Rl are source and load resistance respectively.

No worries so far.

Then he goes on saying that if we want to optimize the Q of the tank circuit with source/load resistance fixed we need to change Xp thru' the L or C of the circuit. Fair enough.

No comes the tricky bit: He than concludes (if I've read it correctly) that the best way of doing this is by INCREASING the capacitance...

I'm not an expert, I'm just starting of, however, from what I heard and tried before, it seemed to me that increasing the L is the better way.

I thought the more inductance we have the better the Q of the tuned circuit will be.

Mathematically he seems correct if one looks at his example:

changing from L=50nH, C=25pF to L=2.5nH and C=500pF @142.35Mhz the Q

of the second combination seems higher (load resistance of 50R).

Could someone enlighten me, have I misread anything?

regards, ference, fkish@attila.mtx.net.au

I have a Memorex TM-4010(made for Tandy) Screen TV(for ATV) that has
recently lost it picture and Sound.

I checked fuses on the power supply and one near the Flyback transformer.
I feed video and audio from a VCR to the "F" connector on the back.
Nothing. I then tried feeding audio and video from the RCA jack on the VCR
to the RCA jacks on the TV. I then get audio but no video.

My first guess is the tuner has died. Is there anything else I should try
before buying a tuner?

Where is a good source for TV tuners?

1039. Schematics going to a web page

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-07 00:00:00 UTC
From: kmiller@airmail.net
Message-ID: <4f9a50$ovu@news-f.iadfw.net>
Source record: 107457

Hello again, guys!

Well, I asked before I posted the schematic and got many good suggestions about where/how to post the schematics. Now that I've posted the first one, everyone has been very helpful except for a few flames from those who didn't appreciate me using up the bandwidth in the newsgroup. I knew it might be a hardship on some folks, that's why I asked first! Wish they'd have said something before I did it!

To accomodate those who don't want them on the newsgroup, I'll be sending them to a gentleman who offered to put them on his QRP web page. When I finish cleaning up the scans, I'll send him the files and you can find them there when he has time to upload them.

If there is anyone who doesn't have access to a web browser or can't get to them, let me know and I'll put the drawings into one big zip file and send them via email. The whole lot of them will be around 250Kb, so it won't be unbearable.

Hope this works, I'm sending this note with Eudora and I've never tried making a mailing list before! I'll drop a note on the newsgroup for anybody who misses it. Thanks for your patience and suggestions.

The web page to watch belongs to:

John R. Cunliffe N2NEP
cunliffe@frontiernet.net
http://www.frontiernet.net/~cunliffe

Keep an eye out for it, maybe the schematics will appear there in the next week or so. Make a bookmark!
73,
Kerry Miller

1043. ? Low-/Bandpass for 144MHz and 432MHz

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-08 00:00:00 UTC
From: guenter.koellner@oen.siemens.DE
Message-ID: <311A1E19@SmtpGate.Oen1.Oen.Siemens.De>
Source record: 107327

Hello,

I was looking for a long time for designs do built tube amplifiers for 144MHz and 432MHz which are able to carry my GS35B providing some kW output. Now I found suitable and they are just under construction. The days ago I thought about the third harmonics and I think I need some lowpass or bandbass filters.

Of course I know that caveties are the best, but they are too heavy. I would need some designs using standard L/C combinations. For the input I need filters which can run with about 200W, so some standard designs could be used. But for the output I need designs which are able to carry 4kW. I remember a design from ON5FF for his 2*3CX800 144MHz amp, he uses heavy silver plated copper tube as inductance and short pieces of semi rigid as capacitances.

My question: do you know anything else, especially for 432MHz?

NB: A simple calculation told me that if I have say 40dB suppression of the third harmonic and 4kW output it is 0.1W at the harmonic... This should be suppressed additionally about 10-20dB.
And: If I have 0.5dB loss that is 435W loss... Some people would be happy if they could reach the power that I would loose, hi. If I allow 100W loss in the output filter thats about 0.1dB and 50W about 0.05dB, so insertion loss should be below 0.1dB

1045. HELP SC filter IC's

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-08 00:00:00 UTC
From: andy_w@sn4707.oldham.gpsemi.com
Message-ID: <4fcgi0$qsg@nnews.Oldham.Gpsemi.Com>
Source record: 107329

Does anyone have any information on a couple of switched capacitor filter IC's the S3529 and S3528 which are made by a company called AMI. They are highpass and lowpass filter IC's. I'm really looking for data sheets and also for a distributor in Great Britain.

The chips are used in an audio filter designed by G3ISD which appeared in the BARTG magazine datacom in autumn 1989/ January 1990. I believe that a kit for the design was available at the time. Is it still available?

Any help would be appreciated.

1046. 813 Xmtr for 160M

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-08 00:00:00 UTC
From: mannd@candw.com.ai
Message-ID: <287cc$63336.319@luzskru.cpcnet.com>
Source record: 107330

I would very much appreciate any advice or opinions about constructing a crystal controlled cw-only transmitter for 160 meters. I have 2 brand new 813's and sockets, lots of other "junk box" parts. My idea is to have a very simple but high power cw transmitter to use for cw QSO's around 1.835mhz. If there is another "window" for 160M that I should use (like for JA's), perhaps I could come up with a 2 crystal design.

Thanks in advance es 73's
Dave, VP2EHF

You might consider that increaseing the inductance also may increase the
series resistance of the coil.

I am re-building my 3-1000 amplifier into a table-top cabinet and am rebuilding the power supply also. I am getting rid of the plate transformer. It is built for Gates Radio and is about 6,600 volts @ 1 amp, or 3,300 volts @ 2 amps. I use it at 3300v for a 3-1000. This brute weighs probably 80 to 90 pounds and is about 18" X 9" X 20" high. Asking $100. I'll drive an hour or two to meet you. Or you can pick it up and see it in service first. If you are planning on going to the Orlando hamfest the weekend of 17 February, I can meet you there.

This antenna was up last field day for the weekend, and has never seen
any other service. I have a spare trap, the instruction manual, a few
spare trap end caps, and asst. hardware. It is presently partially
assembled (elements and boom). I can leave it that way to save a person
the trouble of re-assembling it. This is in very good shape. I bought
it from a guy that had stored it in his garage and never assembled it.
I am getting rid of it because I don't have room for it on the tower.
I presently have a 3 el 20m monobander up. Meet me at the Orlando hamfest
17-18 February, or other arrangements. $125

1053. FRG9600 Recieves HF??

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-08 00:00:00 UTC
From: "Michael G. Reiney" <mreiney@hevanet.com>
Message-ID: <4fckjm$rhr@vista.hevanet.com>
Source record: 107467
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I've been poking around in my Yaesu FRG9600 receiver. Nominal range is 60-965 MHZ. There's a control line labeled /OPTION. When you ground it, the display tunes from Zero to 999.999 MHZ. This line goes to the connector to a missing and undocumented option. There's a place for another antenna connector also going to this option slot. The BAND module has three extra outputs labeled HF1, HF2 and HF3.
Looks like there might have been an option to extend the coverage down to HF.

Was this option available elsewhere? Can documentation be obtained? Has anyone tried to reverse engineer this and build such an option?

I'm also looking to buy the TV option.
I need the Vacuum Fluroescent display. Mine is busted.

Thanks, Miker

Can't tell you much about the windows on 160M, but a pair of 813's will provide 1KW input on CW. RCA's recommendation for these tubes was +2,250V on the plate and +400V on the screen.

You can either key the cathode of the finals (by means of a center-tapped filament transformer) or the oscillator itself. If you key only the stages ahead of the final, you'll need either a bias supply, about -160V, or a clamper tube in the screen circuit. Alternately, you could use grid-block keying and key the oscillator, driver(s) and final simultaneously (preferred, in my opinion).

Depending on the layout, the 813's may or may not need neutralization and/or parasitic suppressors. Also, either push-pull or parallel operation would be fairly easy to implement due to the single-band design.

This transmitter will be operating straight-through, so be sure all stages, particularly the oscillator, are well-shielded from the high-level energy at the final.

How much power, and what modulations are you going to amplify?
I note you are posting from outside the US, so I won't belabor
the Type Acceptance that would be required here since that doesn't
apply in your case. But we still need to know how much power you
want, the strength of the driving signal, and the type of modulation
in order to answer your question properly.

In general, you use the same type of circuits commonly used for
the lower part of HF, just with some scaling of tuned circuit
values. For modest power, up to the 100-200 watt level, the
amplifier would commonly be solid state. At higher power levels,
vacuum tubes would normally be used (though you can build higher
power amplifiers with solid state too).

1061. RE: Anyone else read Bowick's RF circuit Design?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-09 00:00:00 UTC
From: ccurtis@avionics.ITt.COM
Message-ID: <311B7F1A@avint4.avionics.itt.com>
Source record: 107332

I too have Bowick's book and find it to be one of my best references.
I rarely see RF circuits explained in such a through, clear way as
in Bowick's work.

Bowick is correct that increasing the capacitance (decreasing the
inductance) of the tank circuit increases the loaded Q. As you
can see in the formula Q=Rp/Xp, decreasing Xp results in higher
Q. For a capacitor, Xp decreases with increasing values of
capacitance (Xc=1/jwC). For an inductor, Xp *increases* with
increasing values of inductance (Xl=jwL). Trust the equations;
they are impartial.

Taking the subject further, practical inductors have a much higher
series resistance, Rs, than capacitors (see top, left page 36).
This series resistance increases for *larger* values of inductance
(more windings=more resistance). The series resistance reduces
the Q of the inductor (Q=Xl/Rs) and transforms to an equivalent,
parallel resistance (Rp) shunting the tank circuit. The equivalent
parallel resistance decreases as the Q decreases (Rp=(Q^2+1)Rs),
thus loading the tank circuit even more than the ideal inductor.

I hope this helps.

From: Ference Kish <fkish@attila.mtx.net.net>
Subject: Anyone else read Bowick's RF circuit Design?

Hi!

I've just started reading Chris Bowick's RF Circuit Design.

I quite like it and recommend it to others, however, there is something
that
is puzzling me.

On pages 34 and 35 the book discusses the loaded Q of a resonant
circuit; explains the effect of the source and load resistance on
the Q of the tuned circuit.

Where I got a bit confused is Eq 2-6 onward. Bowick says that the
Q of the circuit is

Q = Rp /Xp

where Rp is (Rs * Rl) / (Rs + Rl) and Xp is the inductive/capacitive reactance, Rs and Rl are source and load resistance respectively.

No worries so far.

Then he goes on saying that if we want to optimize the Q of the tank circuit with source/load resistance fixed we need to change Xp thru' the L or C of the circuit. Fair enough.

No comes the tricky bit: He than concludes (if I've read it correctly) that the best way of doing this is by INCREASING the capacitance...

I'm not an expert, I'm just starting of, however, from what I heard and tried before, it seemed to me that increasing the L is the better way.

I thought the more inductance we have the better the Q of the tuned circuit
will be.

Mathematically he seems correct if one looks at his example:

changing from L=50nH, C=25pF to L=2.5nH and C=500pF @142.35Mhz the Q

of the second combination seems higher (load resistance of 50R).

Could someone enlighten me, have I misread anything?

regards, ference, fkish@attila.mtx.net.au

You might try feeding *RF* to the tuner. That's what the F connector
is for, RF not video. But that's probably what you meant to say anyway.
Now you've got audio, so you know the TV is getting power. You don't
have video when you feed video to the set (I'm assuming here that
you're *really* feeding video to the set, and not just RF to the
wrong port). Now the direct video input is *after* the tuner, since
video is the *demodulated* RF from a TV transmission, so whether the
tuner is bad or not is irrelevant, you've got video display problems.

Do you have a raster? To check that, turn the brightness all the way up,
the screen should turn grey. If it doesn't, you may have a high voltage
problem, or an open filament in the CRT. If you do have a raster, then
you've got video amplifier problems. (This could be as simple as a *switch*
set incorrectly to tuner when you are feeding direct video, or vice versa,
or it could be an actual video amplifier problem.)

In any event, forget the tuner for now, get the video display to
work first, then we'll see if there's a tuner problem.

>
>
> Could someone enlighten me, have I misread anything?

Two things are at work here. First, when the value of C is increased, the value of Xc *decreases*, but when the value of L is increased, XL *increases*. Now since Q is Rp/Xp, the *smaller* we can make Xp, the higher the resulting Q. The second thing at work, and not shown in this example, is that most of the circuit intrinsic R is in the inductor. All other things equal, reducing L also reduces intrinsic R. Now that's usually only significant for lightly loaded circuits, but it is another factor favoring high C low L circuits. As Q increases, so do circulating currents, and the intrinsic R of the circuit begins to play a larger role in ultimate Q.

Gary

Message-ID: <823880516.28618@pinetree.microserve.com>
Source record: 107337

I've just come across an IC in an old National data book that looks like a good candidate for building a stable VFO or PTO. It's the LM175 (derated versions are 275/375). This is an oscillator/buffer combination and the specifications regarding stability are pretty impressive:

Parameter Conditions Typical

Power Supply Rejection 5V < Vcc < 10V 0.1 ppm / V
Temperature Rejection -55C < Ta < +125C 0.05 ppm / Deg. C
Load Pull short <= RL <= open 0.01 ppm

Seems to me it would be much easier to compensate an oscillator built around this IC, because the chip would eliminate many of the potential variables and problem areas of a discrete design.

Does anyone know if this IC is still available, and does anyone here have any experience using it?

>I have heard that the HV supply leaves a lot to be desired and that the
>tubes in the amp are not running at their real potential. Does anyone
>have any info on how to improve the HV supply in this amp?

I did a few PA designs for Heath. Let me say this. The SB-220 was designed to run 1 KW INPUT, or 600 watts out on carrier, and 2 KW PEP SSB input, or ~1200 watts PEP (no more than 600 watts average) out on SSB. The cooling, transformer, and other things are perfectly selected if you follow the manual. If you try to run the full capability of the 3-500's, the entire amp needs re-designed.

>I suspect that the caps may be old. Does this sound like it could be
>the problem?

Not if the amp's RF output isn't "humming" excessively on a single tone carrier (CW keydown) test. How much is it dropping? It could be normal. That isn't the stiffest supply in the world. And what type of house wiring are you using?

Yeah right, and photons come down from space and ruin tubes when the amp
is on standby. And fuses work better than electronic overload circuits,
and we can spin a bad tube in a lathe to straighten the filament or grid.

And (as Garth said) monkeys fly out of your butt!

>>These dummy loads work well past VHF frequencies and handle 2 watts
>>OK, everybody flame me now. N6OTQ

>I'll bite...
>"VHF frequencies" = very high frequency frequencies

Actually, the first post was correct. The phrase "Very High
Frequency" (abbreviated as "VHF") is an adjective. Despite the fact
that we often treat it as a noun, such use is grammatically incorrect.
"VHF" must be followed by the object it modifies, such as "band",
"frequency", "transmitter", "antenna", etc.

Now, who can find the error in this sentence: "I are a nit-picker."

:)

Ference Kish (fkish@attila.mtx.net.net) asked some questions about understanding Q of a circuit. There have been some good replies, and I'll try not to just repeat what they've written, but maybe a little different viewpoint will also help.

You can define Q as the energy stored in a resonator divided by the energy lost per radian of oscillation (or 2*pi*energy stored/energy lost per cycle). That definition of Q is valid for any resonator, be it mechanical, acoustical, lumped-electrical, transmission line, or cavity -- or others.

So, in a tank circuit connected to a load (including also resistance in a source if that's appropriate), you can figure the power dissipated in the load(s) by knowing the voltage across the resistive part or the current through the resistive part. From the power and frequency, you can get the energy dissipated per cycle or per radian. (You want the _average_ per radian; don't try to use some particular radian of the cycle, cuz some have less energy dissipated and some more.) And in a lumped element tuned circuit -- L-C circuit -- the energy stored is also pretty easy. The energy "sloshes" back and forth between the L and the C, and twice per cycle essentially all is in the C -- at voltage peaks -- and 90 degrees out of phase with that, twice more, all is in the L, when the capacitor voltage is zero and the inductor current is max. If you know either the max voltage or the max current, you can get the stored energy easily. It's just V(peak)^2 * C / 2, or I(peak)^2 * L / 2. You do have to be careful to understand that that's the peak voltage across the capacitor and the peak current through the inductor -- some circuit configurations can confuse this a little. For example, with series resonance, the voltage across the (L + C) can be very small compared with the voltage across the L or the C individually.

OK, in the case Ference mentioned, there is a constant peak voltage, for a constant power dissipated in the net load resistance, since the generator and load are each in parallel across the parallel tank. So, to increase the Q, we need to increase the energy stored in the tank under the same conditions. And we do that by making C bigger, so that the V^2 * C / 2 gets bigger.

If instead you had a series circuit of generator, L, C, and load resistor, then for constant power in the load, you no longer easily know what the peak capacitor voltage is. But you do know that the RMS current in the load is constant, and since it's a series circuit, the current in the tank is the same as the load current. NOW it's obvious that you must increase the INDUCTANCE to get higher Q, because that increases I^2 * L / 2.

By the way, for most practical inductors, for a given volume and core material, the unloaded coil Q for a good design is quite insensitive to the inductance. That is, if you have an air-core coil 5cm diameter and 10cm long, you can get pretty close to the same Q over perhaps a 100 to 1 range of inductances. That's the unloaded coil Q at a particular frequency, and of course not the same at all as the loaded tank Q discussed above.

This just scratches the surface, but I hope this energy-based viewpoint helps out. With it, you can more easily look at other resonant structures and compare and contrast them to the (perhaps) more familiar lumped LC. And you can understand easily the loss in a filter by knowing the unloaded Q of each resonator and its loaded Q...

Greetings!

Thanks for all of your E-Mails and posted responses.

Just got a winning suggestion, well, a couple of 'em, actually, that make fundamental sense to me...

I think I'll put a second battery in my 4x4 and use my favorite Atlas 210x when 'wheeling and "car camping"...

and I'll go for a kit like the NorCal 20m/75m SSB QRP rig for backpacking.

Great! Thanks again for all of your inputs and recommendations!

-- Dave

P.S. BTW, I got nothing but praise for the MFJ SSB rigs, even though it looks like I'll probably not go that route.

1077. PLL loop filter questions and idea

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-09 00:00:00 UTC
From: willmore@whelk.cig.mot.com
Message-ID: <willmore.823905417@whelk>
Source record: 107348

It seems that every time I look for information on PLL loop filter design, they focus on simple implementation of the loop filter. Is it because simple one or two pole filters are the ideal filters for this use or is there some other design constraint involved? The filter only has to work in the audio range--from my understanding. Would a brick wall, low pass filter of a high order be a better solution? What if you could widen the passband while tuning and narrow it down once you have aquired lock?

Maxim has some nice eighth order switched capacitor filters which could easily fill this role. They are clocked at 100 times the highest passed frequency and are available in the three classic filter topoligies. It would be easy to put in a 1MHz clock with a 10x prescaler for a wide passband and then increase the prescaler value (eight bit counter) when the PLL has locked. Would this do what I think and decrease phase noise?

Just a few thoughts and questions. BTW, anyone have a good VCO design for 60.7 to 64.7 MHz? :)

Cheers,
David N0YMV

Mine is labelled differently, from a Canadian manufacturer. It is cheap
and works well.

The Ramsey FM25 is expensive and in kit form, but works _very_ well. The
1404 has a varactor in parallel with the tank capacitor, and the Ramsey kit
uses that as the VCO in a PLL; it DIP-switch sets to a standard FM
frequency and does indeed stay there.

Any ham uses for these things? I don't know if multiplex transmitting is
legal on the ham bands.

Since the Motron TXiD system connects to discriminator output, it is
only sensitive to variations in carrier phase/frequency, and
insensitive to variations in amplitude.

>Gine Motron a call and they will send literature. I believe they sell a full
>manual for $10.00 which has both a good technology description as well as the

I had an excellent chat with Don Moser of Motron on this topic, and he mentioned his new web page: http://www.motron.com.

Bottom line is: not every radio is certain to have a unique ID, TXiD is a very powerful tool as part of evidence collection but can not be treated as infallible.

The error is you left the J off. The correct phrase is "JI are a
nit-picker" not "I are a nit picker".

circuit
> will be.

This is often confusing (to me as well), because whether you use R/X or X/R depends on whether you're talking about a parallel or series circuit. These definitions of 'Q' are just derived from the more fundamental meaning (ratio of 'lossless' power to power dissipated), so it helps to go back to the fundamental meaning when thinking of X's and R's. In a parallel tuned circuit, such as the one in your example, the voltage across the circuit is the independant variable (kind of...), so to increase the ratio of lossless power to dissipated power you need to increase the ratio of current thru the X's to current thru the R. You do this by decreasing the X's (higher C, lower L). Another way to look at this is that lower X's in a parallel circuit will shunt the voltage across the circuit faster as you move away from resonance, thus giving the sharper peak of a higher-Q circuit.

For series circuits the situation is reversed, with current being the independant variable (again, kind of...). Here the way to increase the ratio of lossless power to dissipated power is to increase the voltages across the X's by making them larger (lower C, higher L). Then as you move away from resonance the dominant X (the one that's rising) will reduce the current faster, resulting in a sharper peak once more.

I know I've done a lot of hand-waving here, but I've tried to explain it in an intuitive way. Hope it was helpful.

BTW, I think Bowick's book is great.

73,
Mike, KK6GM

I believe that your equation is for the loss tangent which is 1/Q.
"Q" is the ratio stored to dissipated energy, and should be
Q=X/R. Clearly X and R give rise to energy stored and dissipated
respectively. I think it's a typo in the book.

Vhf or UHF ???????????? The VHF is easy, as the TX and RX are two separate strips. Just cut a couple of jumpers, add a couple of jumpers and tada - instant repeater. (Complete with built in desense and the shielding is inadequate) The UHF version is a bit more complicated. The TX oscilator is derived from the RX LO. You have to change the offset xtal and rewind a coil to shift the offset from +5Mhz. to -5Mhz....The rest is easy. Has a lot of problems with RF getting into the PL encoder on the UHF conversions. Don't do them anymore.... The internal shielding really isn't quite good enough to make a real repeater out of it....Additionally, the UHF version is real flaky, the LPA and IPA decks fail often and are real expensive and hard to find. It is easier to build a repeater from a Master II GE but I would still separate the transmitter and receiver into separate units. I have built 15 or 20 of them that way.

>(This question comes up because I have ready access to some
>200 watt power supplies that have been "pulled" from PCs...)

Switchers *can* work fine for powering amateur equipment, witness the Icom and Yaesu switching supplies. *However*, the switcher used must be designed to work with the radio in several respects.

First, it must maintain regulation across the wide current load demands from a few milliamps to 20 amps that a radio may present. Many switching supplies require a *minimum* load or they lose regulation (often disasterously by going to a very high voltage).

Second, it must adequately suppress switching hash. Switchers are inherently generators of high harmonic content. This has to be suppressed or you'll pickup the hash in the radio.

Third, the power supply must be tolerant of a high RF environment. Switchers are often sensitive to stray RF, which can cause them to lose regulation (sometimes with disasterous consequences).

Now the PC power supply presents special problems in this regard. It requires a minimum load on the 5 volt bus to function. So if you're going to use it to power 12 volt equipment, you're going to have to put a "dummy load" on the 5 volt bus to make it work correctly. Most PC switchers require at least a 2 amp draw on the 5 volt bus to function correctly. And of course the PC supply can only source 2 amps on the 12 volt line, so it is *really* only a 24 watt 12 volt supply. Most of that 200 watt rating is on the 5 volt bus where it normally supplies *large* amounts of current.

I'd just strip them for parts. There are some good parts inside there, including some nice capacitors you could use in the power supply of your tube amplifier projects.

From: rmwatson@eskimo.com
Message-ID: <DMKsKr.I1p@eskimo.com>
Source record: 107366

I am planning on building a Yagi antenna, probably for 20-10 meters, and want to make a miniature version, (using helical wound elements), and probably a 3 element version.

I "understand" most of what it will take as far as measurements are concerned, including the electrical lenggth vs. the physical length of the wire used on the elements. I will be using fiberglas elements that are at a slight taper, and each side will be approximately 4-5 feet long, for a total (at least of the reflector for approximately 8 feet).

Anyway, I am interested in any information from anybody that has built (or for that matter attempted to build) a like project. I am also interested in locating information as to the whereabouts of books on the aformentioned project. I found very little in the way of hf/vhf helical beams in the ARRL Antenna Handbook (1995) version.

Thanks for your help

I was avoiding going into a lot of detail. Of course you are correct in that
the TxID-1 does not "read" any amplitude information, and is absolute by any
interpatation, but it is a GOOD tool to hope "prove" abuse by a given user.

Additional information like DF'ed location, attenuated readings (lots of
signal strength with attenuators in front of the guys house), recordings
(TxID-1) of the same trasnmitter when properly used (talking with ID/callsign)
are all inporatant pieces.

Also tools like APRS to let multiple stations plot a signal bearing and share
the data "quickley" over packet can also be of greate use.

The problems in Kansas are, sigh, not unique. I can tell you that the same or
similar problems exist in the Balt / Wash area as well. It is unfortunate
that we must spend time dealing with these issues, but they do keep coming
back.

We are also istalling seperate doppler type direction locators at all of our
recieve sites (12 +) and will be able to "localize" via the basic system
before real DF work with beams and similar comes into play.

If the author above is referring to a Kenwood TM-241, then I have the same problem, and would love to see an answer to his query. Sometimes the display looks fine... Right now, all of the horizontal segments are on, and a few of the vertical ones. It is *really* annoying, but I don't want to give up usage of my packet radio to get it fixed. It seems to have no affect on operation, just the display.

Thanks.

: It seems that every time I look for information on PLL loop filter design,
: they focus on simple implementation of the loop filter. Is it because
: simple one or two pole filters are the ideal filters for this use or
: is there some other design constraint involved? The filter only has to
: work in the audio range--from my understanding. Would a brick wall, low
: pass filter of a high order be a better solution? What if you could widen
: the passband while tuning and narrow it down once you have aquired lock?

The problem is that the filter is part of a closed-loop feedback control system. If you have unity gain and net 360 degrees phase shift in the loop, you are going to have oscillations. Since high-order filters have large phase shifts where their gain is still high, they aren't appropriate for use in a closed loop.

Just type the ascii characters A-D into the dial string. For example:

ATDT 1234ABCD

will dial the desired digits. Upper or lower case will work. I occasionally use this to send DTMF control codes to repeater controllers that have these digits in their control codes. Of course, you must first disable call progress detection on the modem or it will try to look for the dial tone before dialing. I do this as follows:

ATX0=0

This works on the older modems, and I have tried it on my Zoom modem.

I'm not a PLL expert but have worked with some simple stuff at 1Khz. I believe the design of the filter will affect the capture and lock range of the PLL. For example, too sharp a filter could easily lose lock (If I understand it right). However I think the gear shifting filter idea might work just dandy. Although depending on your application, there usually isn't much need for a really whopper filter in the PLL.

Just my thoughts

It all depends on what you want to run with your power supply. Switchers do introduce some noise, but most are well filtered and out of the audio and amateur bands. The hard part is finding a switcher that can handle the load. For example, a 200 watter is 15 amps approx, barely enough for a solid state HF rig. Also note that your 200 watt supply is more than likely only rated for an amp or two at 12 volts. Usually all the ooommmpph is in the 5 volt supply.

I am interested in making a remote controlled toy robot that has a relatively high BW (~ 19.2 Kbaud) full duplex (if possible) connection to a computer base station.

I don't want to violate FCC regulations, and I don't want to have to get a license. Except for the 900 - 928 MHz spread specturm band, is there any portion of the spectrum that allows unlicensed usage of this type ?

Also, what do frequencies are used for commercially available radio controlled toys ?

How would I find information on FCC regulations on the RF spectrum < 1 GHz ?

Thanks in advance.

1107. Help design coil for coupling 2 amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-11 00:00:00 UTC
From: opworld@worldnet.fr
Message-ID: <4fkhdu$4e9@aldebaran.sct.fr>
Source record: 107378
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

Hi everybody

I would like to add the power of two identical amplifiers in 80-120MHz range with 300W each.

I don't know how.

I believe that you have to apply signal to each amplifier (invert one signal like LF amplifier ?) adapting impedance (50 ohms -> 50 + 50 ohms). For output add power with impedance matching.

Help will be greatly appreciated !

Regards

Have
a nice opworld@worldnet.fr

Hello all,
I amlooking for some software to use all the functions of the mfj
1278 multimode tnc. I am sure I saw somewhere a program described that does
all the functions (but much better) than multicom 3.1. Unfortunately I did
not bookmark the site or program name, can you help????.
regards Peter L. Williamson VK4AWP.

I'm using multicom, but I have a friend using a program from Canada
called "Skyrider". I don't think it supports fax and maybe other
video modes though. He said that he saw it in an ad in a magazine.
Sorry but that's all I remember about it.

Message-ID: <4fk0ivcpl1@mhade.production.compuserve.com>
Source record: 107381

Thank you all for your very nice comments about my book RF Circuit Design. I'm glad that you have found it useful. I originally wrote the book because I was unable to find a text on the topic that could adequately explain the in-depth RF theory the way I felt it needed to be explained---with detailed example problems and step-by-step solutions.

The book was originally published by Howard W. Sams, which was later bought out by Macmillan, and is still going strong.

Kish, Curtis, and Coffman et.al. did a great job of providing further explanation of Xp as it relates to Q of resonant circuits.

I am considering an update to the book (2nd Edition) and would be interested in any input, suggestions, corrections, etc. that any of you might have. Perhaps we can make it an even better reference book in the future!

Thanks again! Enjoy!

Peering inside of an amplifier that I aquired at a military surplus store, trying to figure out what band it is for and what the power output is. It takes a 28v DC power supply. Has 'N' type connectors for in and out. Made by 'TPL Com Inc.
Inside there are five identical circuit boards tied together, with the heart of each board appearing to be Motorola brand finals. White ceramic looking discs, about 1/2" in diameter and 1/8" thick. On them is the Motorola logo and the following:
MRF327 (on the top line) and 8851 directly under the top line. Any techies out there know what frequencies these may operate at, and at what power output?
I really have no idea what I have here. It is modern, and brand new. Just don't know how to figure out what it was made for.

If you were lucky, and the phase difference is not too bad between amplifiers, a simple 1/4 wave line from/to each amplifier of 75 ohm coax will function as splitter and combiners.

50 -> 1/4 wave 75 ohm coax -> 102.5 Ohms
Use a tee to join both and you're backto about 50 ohms!

Enjoy!
Tom

Although I design these things for a living, I'm cautious about calling myself an "exspurt". But I'll take a poke at this...

In article <willmore.823905417@whelk>, willmore@whelk.cig.mot.com says...
>
>It seems that every time I look for information on PLL loop filter design,
>they focus on simple implementation of the loop filter. Is it because
>simple one or two pole filters are the ideal filters for this use or
>is there some other design constraint involved? The filter only has to
>work in the audio range--from my understanding. Would a brick wall, low
>pass filter of a high order be a better solution? What if you could widen
>the passband while tuning and narrow it down once you have aquired lock?
>

The phase shift through the filter affects the ability of the loop to respond properly. We generally set our loop filters to 20% of the reference frequency because of this. Yes, a higher order filter will extend the flat part of the response out closer to the reference frequency, but the phase shift changes as well.

Of course, according to some writers (like Ulrich Rhode) when you try to build a 2nd order, you really build something higher order anyway.

>Maxim has some nice eighth order switched capacitor filters which could
>easily fill this role. They are clocked at 100 times the highest passed
>frequency and are available in the three classic filter topoligies. It
>would be easy to put in a 1MHz clock with a 10x prescaler for a wide
>passband and then increase the prescaler value (eight bit counter) when
>the PLL has locked. Would this do what I think and decrease phase noise?

I'd be afraid of clock feedthrough getting on the control line. You might want to wrap an elliptic lowpass around those to get rid of the clock, but then you're introducing another filter, more phase shift, and more things to be concerned about. When you try to figure out how much voltage from the clock you can stand on the VCO control line without getting horrible spurs, you can scare yourself pretty quickly.

>
>Just a few thoughts and questions. BTW, anyone have a good VCO design for
>60.7 to 64.7 MHz? :)

Have you heard of "PADS"? It is a circuit schematic editor, and PCB layout program. I believe it comes in a Sharware or lite version. I had a copy but played with it very little. It does do the job though - definately not as well as a high dollar program, but it does work. I did have some problems getting it to run properly, but my system was lacking memory and running on a 386 chip. I don't know how you can find it, but it should be out there somewhere. It is definately worth trying out if you can get a copy. Some neat features are the ability to interface with SPICE and has several export/import formats for both schematics and PCB layout.

From: billj@calweb.com
Message-ID: <4flm5r$fg7@news.calweb.com>
Source record: 107391

Where can I find information on the following?
I have a couple of "StaLoc" YIG filters made by Eaton/Yig-Tek.
There are two YIG filters in one magnetic housing arranged so that
one of the YIGs can be tuned with an offset from the other.
The base of the filter has some electronics with four coax connectors and
five feed-through connections labled e1 through e5.

What I need to know is, what signals and what voltages go to each connection.

These filters are miltary surplus and have the following labeling:

12115 ASSY 7513-7172-1
12115-7513-7172-2
SERIAL NO L143-5d
DATE CODE 8807 REV D

If I can figure out the connections I want to use them with my homebrew
microwave equipment.
Thanks

>Disclaimer: I don't speak for Motorola.

PLL 'Filters' don't actually filter as such. They serve to set the
loop bandwidth and damping factors and as such only need one or two
poles. For basic loops there is nothing to be gained by going to
higher order filters. The PLL can only clean up phase noise closer to
the carrier than the loop bandwidth. Phase noise needs to be
minimised at start by using as wide a loop bandwidth as possible and a
VCO with an inherently good phase noise performance in its own right.

Don't even think of using switched capacitor filters in PLLs. There
could easily be horrible interactions between switching components and
loop frequencies!

You have a great opportunity ahead of you. Maybe I can help. I've lofted an
80m wire antenna with helium.

>Here are the burning questions for the day. How many pounds will a 12' x 8'
>surplus wx balloon, inflated with two full-size tanks (approx. 240 CF/tank)
>of helium, carry to a height of about 100 feet into the air? We are presuming
>at this point that fishing line would be used to tether the balloon in place
>in order to maintain constant tangency above ground.

For starters, the surplus weather balloon should be fine, provided you don't
fill it tight. June weather tends to be warm, and helium will expand quite
alot in warm weather. I experienced several bursted balloons. I used 50/50
latex and neopren (SP?) at $4 each. These are very strong and reusable. They
measured 4 1/2 feet across.

>We want to determine how heavy guage wire can be used for the vertical. For
>that matter, if we hoist the entire 90 degree electrical length, I assume it
>will eliminate the need for a capacity hat.

I used 18 guage stranded wire, a little light for this type of duty, but it
worked for up to 100 watts. I never tried more power than that. It goes
without saying, but the smaller the diameter the wire used, the narrower the
bandwidth the antenna displays.

A few additional notes:

1) Check with your local FAA office. I found out that my balloon/antenna
could not be over 100 ft above average terrain, if located within 25 miles of
ANY airport or airstrip, and teathered.

2) The FAA requires written notification if the balloon exceeds 100 ft in
height.

3) The FAA requires illumination of ALL teathered balloons after dusk.

Your local FAA office may have different information, so check with them.

Teather your balloon to prevent movement of the antenna. This movement WILL cause SWRs to go crazy, even slight movement.

Have fun, and let me know how it works out for you.

Do not post them here. This is not a binaries group and news admins don't
like hidden binaries groups; they are even more likely to block them than
overt binaries groups.

JPEG is not a good format for line drawings. TIFF FAX, PCX and GIF are
all better at handling them (JPEG is very good for natural images, though).

>Disclaimer: I don't speak for Motorola.

You should talk with some Mot. engineers in Illinois they could
provide you with good info.

The problem with the Maxim filters is noise.

High order filters are more prone to ringing which increases
settling times.

Mot. has some good books on PLL's get them.

Changing the loop BW is sometimes done if needed. Adds
complication.

The 1953 ARRL Handbook has an excellent design for a single 813 transmitter. It uses a 6AG7 oscillator, 6L6 driver, 6Y6 clamper and an 813 as Power Amplifier. A Classic 1930's design!

Fair Radio in Lima Ohio has the ART-13 available in surplus again for $150. It covers 2-18 Mhz
(and is easily re-worked for 160 thru 10 meters) and uses an 813 modulated with a pair of 811's. You might have more fun rebuilding the ART if you just want to run the 813's!

Keep them in the original pairs! G0SNO of the RSGB EMC committee has found that they make excellent RF chokes for heavy AC line currents, with just the right combination of permeability and physical size. Wind the whole line cord about 10 turns through the cone, and it'll be resonant in the mid-HF region. You could even do the same with RG213 for a monster feedline choke.

They don't look pretty but they do work, and scrap deflection yokes are usually available free at the back door of the local TV repair shop.

>ohms). For output add power with impedance matching.

What you need is called a Wilkinson power splitter/combiner. This will divide the drive power equally between the amplifiers, and combine their output powers. Phase is maintained identical through both paths, except for the differences in phase internal to the two amplifiers. That can be compensated by using an adjustable phase shifting network at the input of one of the amplifiers, IE a line stretcher or the like, and adjusting to null reject power. You may also need to be able to control the gain of one of the amplifiers so that you can exactly match amplitude response too, again adjusting to null reject power.

Wilkinson networks are easy to build for a specific frequency. In your range they would just be lengths of coax and a reject load resistor. To cover the entire 80-120 MHz spread without retuning would be more difficult. See any RF handbook for details of building Wilkinson splitters and combiners.

1131. ICOM IC-2SAT HELP!?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-12 00:00:00 UTC
From: NAME: 100623.303@CompuServe.COM;
Message-ID: <4fm7ts$no7$1@mhade.production.compuserve.com>
Source record: 107398
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,uk.radio.amateur

I have just bought an ICOM IC-2SAT minus instuction manual.
can anyone help me with the following points:-

1) does this radio have a tone burst for reapeter use ,if so how
is it operated?

2) my radio seems to have rx 100-200 Mhz and tx 140-150Mhz
but the disply will read 0-1300 Mhz. does this mean it can
be made to receive from 0-1300 Mhz if so how?

3)does anyone know of any other mods or add-on modules for the
2-sat ?

i would be greatful of any help or details on this radio..

THANX

ROB!!!!!

1132. Broadcasting Radio Station Database for you.....

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-12 00:00:00 UTC
From: chuck <chuck@mail.flinet.com>
Message-ID: <4fme8u$bsf@news.flinet.com>

Friend,

A fully functional standalone Broadcasting Radio Station Database for IBM and compatibles with more than 4,000 Radio Station records already. This program covers stations on Longwave, Mediumwave, and Shortwave. Each record contains the Station name, Frequencies, Schedule, Languages, Country, and Continent. The program sorts in same order.

What's needed to get it? Your EMail address and your Postal Mailing address for registration and future information via Post of other Radio Related Database programs. This information will be kept confidential.

If you can read a document written in MS Word(extension is DOC), request the operating instructions for the Radio Station Database Program called Voyageur. You'll get an idea from reading this document of the Voyageur Database and what it does.

Incidently, the program offered with this notice is valid until June 6, 1996.

Hope to hear from you..

Chuck

1136. Press Release - PIC-1 Pro Pack

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-12 00:00:00 UTC
From: itutec@aol.com
Message-ID: <4fmj8c$pbp@newsbf02.news.aol.com>
Source record: 107403

ITU Technologies is proud to introduce the new PIC-1 Pro Pack. This new package is geared toward serious hobbyists and engineers looking for a high-quality PIC programmer at a low price.

The PIC-1 Pro Pack includes:
* the PIC-1 Programmer w/software, cables and power supply (US only)
* the PIC-n-GO upgrade (PIC16C84 processor and data sheet)
* 18-pin ZIF socket upgrade for PIC-1
* 40/28 pin ZIF adapter module for PIC-1

The PIC-1 Pro Pack is _only_ $79US in kit form or $99US assembled/tested.

This package will allow you to program all of Microchip's PICs in the mid-range family (PIC16C6x/7x/8x) with out-of-the-box support! This high-quality package includes everything you will need to begin programming PIC microcontrollers today!

This is the same PIC-1 programmer you have read about in Electronic Products, MicroComputer Journal, Electronics Now, Popular Electronics and Nuts and Volts Magazine.

For those just starting out with PICs, we recommend our PIC-n-GO Package. This includes our PIC-1 programmer with one PIC16C84 EEPROM-based processor and data sheet. This package includes all software, cables and power supply (US only) for only $45US in kit form or $61US assembled/tested. The PIC-1 programmer alone is available for $39US in kit form or $55 assembled/tested.

Please add $5 shipping in North America, $10 to all other destinations.

You may pay with VISA or MasterCard, COD (US only), money order, or your personal check.

See our WEB PAGE for more details and other great products!

I think that Rob has it right. Internet email host names are case
insensitive. (But user names may not be.) Compuserve's mail system will
definitely not bounce this and your host system should get the correct
address from the dns with this name, if it isn't broken. Judging from the
six copies of the posting you sent, I wouldn't bet on that.

BTW, the format of `Best address' which you suggest is perfect for sending
email from one CompuServe user to another Comuserve address but via
Compuserve's Internet gateway, which is a fairly unusual thing to do.

Regards,

1145. Re: Loaded Q

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-12 00:00:00 UTC
From: mack@mails.imed.COM
Message-ID: <9601128241.AA824145910@mails.imed.com>
Source record: 107412

Ference Kish Asked about loaded Q in Bowick's book. I, too, was confused at first when reading Mr. Kish's post. The first time I had to teach this to students who barely understood what reactance was, I had to reread the texts VERY carefully. I missed a couple of subtle points when I learned this subject the first time.

Probalby the biggest problem is the names we use for the circuits. First a RESONANT circuit is by DEFINITION series resonant! As the British say, a circuit composed of parallel elements is ANTI-RESONANT! The two circuits behave decidedly differently and SHOULD NOT be called by the same name (that's what confuses folks).

Let's look at the RESONANT circuit first. It is composed of 3 elements: an inductor in series with a capacitor in series with a resistor (which is composed of the parasitic R of the inductor plus ALL of the load resistance). The formula for Q:

Q= Xl/R

Note that R does not affect the resonant frequency.

Now lets look at an ANTI-RESONANT circuit. It is composed of FOUR elements. It has a capacitor in parallel with the load resistance which is in parallel with a series circuit composed of the inductor and the parasitic resistance of the coil. You can transform this 4 element circuit into the analogous circuit for the resonant circuit. You then end up with a resistance in parallel with a capacitance in parallel with an inductance. The math to do this is too complicated to explain here. Any textbook can do a better job than I can in an e-mail.

For an ANTI-RESONANT circuit the formula for Q is:

Q = Reffective/ Xl

Reffective is the load resistance in parallel with the transformed parasitic resistance.

In order to get the highest unloaded Q you want the ratio of Xl to parasitic R to be as high as possible. This is MUCH easier to do with smaller values of L where you use just a few turns of large wire. The inductance tends to go up more slowly than parasitic resistance when the number of turns goes up! This is a physical effect as a consequence of needing to use smaller wire diameter as you add more turns.

A couple of examples may help:

An inductor with 10 Ohms Xl and 1 Ohm resistance transforms to 9.99 Ohms XL in parallel with 101 Ohms resistance.

An inductor with with 10 Ohms Xl and 0.1 Ohm resistance transforms to 10 Ohms Xl in parallel with 1000 Ohms resistance.

The loaded Q is obtained by getting the parallel equivalent of the load resistance in parallel with the parasitic resistance equivalent. From this you can see that you want the contribution of the parasitic to be as small as possible so that the loaded Q is dominated by the load resistance. This means for a PARALLEL circuit you want the parasitic resistance equivalent to be MUCH larger than the load resistance.

Since we are using a much smaller inductor to keep the ratio of inductance to parasitic resistance, we must use a LARGER C to get the same anti-resonant frequency.

One SUBTLE difference between the resonant and anti-resonant circuits: for a resonant circuit the parasitic resistance DOES NOT change the frequency; for the anti-resonant circuit the parasitic (not the load) resistance changes the frequency!!!

Another thing to note: you need higher Xl for good Q in a resonant circuit as long as the parasitic resistance is smaller than the load resistance, you need smaller Xl in an anti-resonant circuit to get good Q.

I hope this has cleared up some of the confusion.

>for use in a closed loop.

What is important to look at is the loop Bode plot; it is easy to design
a filter to one particular parameter (minimum reference feedthrough OR
fast lock-up time OR ..., etc.) but the real task is to balance between
several conflicting design goals, one of which is loop stability. A Bode
plot of the loop response is important (and not difficult to do) to
make sure the loop is stable. At the same time, be sure to take into
account the changing loop parameters (mostly VCO gain) over the operational
range; you'll need to calculate loop stability at both extremes of VCO
gain to make sure it doesn't break into oscillaton (don't forget to include
overshootas part of the VCO extreme).

Don't forget that noise in the loop filter directly translates to
noise in the VCO output, and more complicated filters tend to be
noisier, which can ruin otherwise good phase noise performance.

Of course, the filter is there to stabilize the loop and minimize
undesired reference frequency modulation of the VCO, so you might do
as suggested in one Motorola app note and design the "right" loop
filter and then follow this with a notch filter at the reference
frequency in order to gain a way to independently achieve both goals.

Also, don't forget I'm a computer programmer and not a PLL designer ;-)

michael silva wrote:
good book. Try KBR (krauss, Bastion, Raab) for more rigor.
One explanation for your confusion is as follows:

f0 = K * (LC)^0.5, K is constant (1/2pi)

given f0, raising C will "lower" L, this I think
you know.

Now remember that an inductor is manufactured from
some REAL world material (usually metal), eg wire.

Same for the cap.

Turns out that the losses in the
cap's dielectric (and any other effects) are much
lower than the losses in an inductor of comparable
impedence. The inductor's losses are almost all
due to the resistence.

Hope this helps.

Greetings to David and the group,

I believe ATV qualifies as a multiplexed signal. So yes, multiplexed signals
are permitted on the ham bands.

INTRODUCING HAM RADIO ONLINE INTERACTIVE!
Now you can post free classified ads, DX openings, VHF band openings
and much more. And with over 10,000 readers stopping by last month,
your thoughts will actually get read at this ham radio web site! We are not
just pointers to cyberspace - we've got actual content - feature articles,
newsletters, product reviews, real-time propagation conditions and more.

The February 1996 edition of Ham Radio Online International Magazine
is available at http://www.accessone.com/~vbook/hronline.htm

Some of the NEW February stories include a review of SkyTel's "2-way paging" system,
radio surveillance frequencies, and the effects of two-way radio operation in blasting
zones.

Ham Radio Online has been selected as a featured web site by America Online
and a Top 100 web site for the month of January by Planet Earth, Inc.
New articles are available now and we add articles throughout the month.

Ham Radio Online has up-to-date news about Amateur Radio from around the world,
feature stories, real-time propagation and auroral condition reports, real-time
earthquake and severe weather conditions for emergency communications planning,
online humor section and the Ham Radio Online Library with fully indexed (find
any section with just a mouse click) Part 97 rules and regulations.

Plus we cover broadcasting, shortwave, scanning generally anything having to
do with radio telecommunications.

And we plan to offer some totally cool new services during the coming months. As
always its free and free of ads.

Thanks to you, we had over 10,000 readers stop by during January!

Please enjoy!

73, Ed Mitchell

>Just don't know how to figure out what it was made for.

Another gentleman described the device itself, and I'll add that the
"8851" means the part was manufactured in 1988. The "51" could mean
Day 51 or May 1. These codes vary, tho I'll bet the military has a
standard, which I don't know.

Fersure don't miss Motorola's Web site:

http://motserv.indirect.com/

There is a HUGE amount of information there, including a lot of nice
downloadable data sheets in Adobe Acrobat format.

Good luck with that rig.

: >
: >I believe that you have to apply signal to each amplifier (invert one
: >signal like LF amplifier ?) adapting impedance (50 ohms -> 50 + 50
: >ohms). For output add power with impedance matching.

: What you need is called a Wilkinson power splitter/combiner. This
: will divide the drive power equally between the amplifiers, and
: combine their output powers. Phase is maintained identical through
: both paths, except for the differences in phase internal to the two
: amplifiers. That can be compensated by using an adjustable phase
: shifting network at the input of one of the amplifiers, IE a line
: stretcher or the like, and adjusting to null reject power. You
: may also need to be able to control the gain of one of the amplifiers
: so that you can exactly match amplitude response too, again adjusting
: to null reject power.

: Wilkinson networks are easy to build for a specific frequency. In
: your range they would just be lengths of coax and a reject load
: resistor. To cover the entire 80-120 MHz spread without retuning
: would be more difficult. See any RF handbook for details of building
: Wilkinson splitters and combiners.

Here are the dimensions for the Wilkinson Hybrid for 88-108 Mhz. Its
center frequency is 97.49 Mhz. You will need two lengths of PTFE
(Teflon) 75 ohm coaxial cable suitable for the power level being used.
Do not use anything other PTFE cable. The length is 54.4 centimeters.
connect in a V configuration. For the splitter to drive the two amps,
at one end of the cables conncect the two center conductors together and
the shieldst to ground, this is your input. At the other end of the two
cable are your two output ports to the two amps. Shields are connected
to ground with the two center conductor becoming the two output ports. A

100 ohm non-inductive resistor is connected between the two output ports. It has to have a dissipation equal to 1/2 of the applied power. For the combiner use the above configuration but the output ports become the input ports for the two amps and the input port becomes the output port. You will need a non-inductive resistor with a 150 watt capability, these are made especially for RF, contact Richardson Electronics for them.

MRF327's are 80W broadband controlled Q transistors for frequencies 100-500 MHz with guaranteed 400Mhz 28VDC performance. The 8851 number is the 51st week of 1988 when they were built. Call your local motorola office and ask for the data sheet; they shouldn't balk at sending it out, just don't tell them the surplus/curiousity story...

Perhaps the ISM (Industrial/Scientific/Medical) band(s) -- there is one
around 2.3GHz, shared with a ham band.

>
>Also, what do frequencies are used for commercially available radio
>controlled toys ?

I know of three bands, to my knowledge limited to one of 2 modulation schemes.
One sold as "FM", where PPM servo control data is FM modulated, and "PCM" where
digital servo control data is sent as a digital code. "AM" has been phased out.
There are some channels in the 27 MHz CB band -- good luck here. R/C flyers abandoned
this band a long time ago due to encroachment from illegal CB voice communications.
(There, I said that as nicely as I could.)
There are some frequencies allocated for R/C in the 50 MHz ham band, you need a
Technician class ham license here. And then there is a band at 72 MHz, between
TV channels 4 & 5. Also, there are toys with low power transmitters operating
under part 15 rules at 49 MHz.

1165. Any Interest in Some Filters?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-13 00:00:00 UTC
From: tayloe_d@sat.mot.com
Message-ID: <1996Feb13.150343.29908@schbbs.mot.com>
Source record: 107291

I have a number of crystal filters laying around that
might be of interest to the experimenter community here.

These are 11.4 MHz available in both USB and LSB. The
passband is about 300 to 2900 Hz, with 5 db of insertion
loss, and 21 to 29 db of carrier supression. These
values represent typical numbers I have seen on several
samples that apparently have been measured at one time or
another.

These filters are composed of a set of three individual
filters that are cascaded. More could be cascaded together
for steeper skirt response. It may be possible to narrow
the response (as is done in normal ladder filters) by using
larger termination load capacitance.

I myself have not used these, so I don't know the terminating
resistance or the load capacitance to get the desired filter
shaping.

If you are interested, I am asking $5.00 per set and I will
pay for shipping. Please indicate if you want Upper Sideband
or Lower Sideband or if you really don't care.

Thanks!

A pair of the ferrite cones can be used as a filter for your phone line -- take a half a dozen turns through the core.

If you had hundreds of these cores, you might find a sculptor who is working with "found" art who could use them.

That's all I've found you could do with yoke cores.

We already know that flyback transformer cores can be used in some toroid applications such as filament chokes.

David A Willmore (willmore@whelk.cig.mot.com) wrote:
: It seems that every time I look for information on PLL loop filter design,
: they focus on simple implementation of the loop filter. Is it because
: simple one or two pole filters are the ideal filters for this use or
: is there some other design constraint involved? The filter only has to
: work in the audio range--from my understanding. Would a brick wall, low
: pass filter of a high order be a better solution? What if you could widen
: the passband while tuning and narrow it down once you have aquired lock?

Just offhand, I would say the varying phase shifts as you moved
across a complex filter would be very unsetting to loop dynamics.

Looking at someone's synthesizer IC the other day (National?) that
brings out a pin called QuickLock which can be used to throw a
shunting resistor in a simple lead/lag network to speed up the
lock time.

: Just a few thoughts and questions. BTW, anyone have a good VCO design for
: 60.7 to 64.7 MHz? :)

Years ago now, I had very good luck using a capacitor at the end
of an ~ 1/4 wavelength of coax to replace the inductor in a VCO,
to get higher Q and thus lower phase noise. Use minature coax, and
just roll it up out of the way.

>1) does this radio have a tone burst for reapeter use ,if so how
>is it operated?

On the 2SAT, 1750 Hz burst could be added if the serial number was below about 9500, also the minimum offset tuning step size needed to be 25 kHz. Here you would need to convert the radio to a european version and install 2 SMD resisotrs. After S/N 9500 or so the offset tuning was made adjustable and the 12.5kHz tuning step was removed, also so was the ability to have a 1750 hz tone burst. The reason was to free enough memory in the CPU to have the adjustable offset tuning steps rather than the original fixed 25 khz tuning in the earlier model 2SAT radios.

>2) my radio seems to have rx 100-200 Mhz and tx 140-150Mhz
>but the disply will read 0-1300 Mhz. does this mean it can
>be made to receive from 0-1300 Mhz if so how?

The radio will actually receive from 110 to 136 aircraft A.M. and 136 to 174 Mhz F.M. Signals above or below this range are usually overloads or images. The tuning ability never stopped in the CPU program, how ever the VCO never had the kind of range the frequency readout would report.

>Frequency" (abbreviated as "VHF") is an adjective. Despite the fact
>that we often treat it as a noun, such use is grammatically incorrect.
>"VHF" must be followed by the object it modifies, such as "band",
>"frequency", "transmitter", "antenna", etc.

Thanks for your correction! I'll be sure to update my dictionaries, which claim "frequency" is only a noun, including the online one (and therefore that "very high frequency" is also, just a particular piece of it):

spot> webster frequency

fre.quen.cy \-kw*n-se-\ n 1: the fact or condition of occurring frequently 2a: the number of times that a periodic function repeats the same sequence of values during a unit variation of the independent variable 2b: the number of individuals in a single class when objects are classified according to variations in a set of one or more specified attributes 3: the number of repetitions of a periodic process in a unit of time : as 3a: the number of complete alternations per second of an alternating current 3b: the number of sound waves per second produced by a sounding body 3c: the number of complete oscillations per second of an electromagnetic wave

and that VHF does _not_ mean "the band between 30 and 300 MHz of the electromagnetic spectrum," as erroneously defined on spectrum allocation charts, but is actually just a modifier.

I've got lots of updating to do: Turns out "dog" and "computer" are also adjectives, as in "dog cage" and "computer screen" - just like "VHF radio" and "VHF antenna." Zounds! Turns out _every_ noun is an adjective. "Noun" is an an adjective when used in "noun list"; it just modifies 'list'!

But before I do that, I have lots of other things to do. I better check the SWR ratio of my HF frequency antenna, because the ATU tuning unit blew an FET transistor, keeping me from tuning all the way up to the MUF frequency. In which case I'll have to go the the ATM machine (and type in my PIN number) to get some money to buy more IC circuits for the TTL logic part of the CPU unit's LED diode (and CRT tube) display driver, since it's all SNAFU'd up.

Too much DC current on the RF frequency (not the VHF frequency) RFI interference blocking choke. Or was it EMI interference, and AC current? I better get out the DMM meter, and follow the trouble-shooters standard SOP operating procedure.

I hate it when that happens.

Very best 73s's, and CUL later.

From: tayloe_d@sat.mot.com (Dan Tayloe)
Subject: Any Interest in Some Filters?

I have a number of crystal filters laying around that
might be of interest to the experimenter community here.

These are 11.4 MHz available in both USB and LSB. The
passband is about 300 to 2900 Hz, with 5 db of insertion

loss, and 21 to 29 db of carrier supression. These
values represent typical numbers I have seen on several
samples that apparently have been measured at one time or
another.

These filters are composed of a set of three individual
filters that are cascaded. More could be cascaded together
for steeper skirt response. It may be possible to narrow
the response (as is done in normal ladder filters) by using
larger termination load capacitance.

I myself have not used these, so I don't know the terminating
resistance or the load capacitance to get the desired filter
shaping.

If you are interested, I am asking $5.00 per set and I will
pay for shipping. Please indicate if you want Upper Sideband
or Lower Sideband or if you really don't care.

Thanks!

Subject: Function and pinout for some RF IC

Hello,

Does anybody have (or may tell me where I can find) the pinout
and the function of the following IC's.

CX 7925 (nothing from Sony's Web site)
TC 5081 (nothing from Thoshiba)
TC 5082
TA 7310
HD 1055 (nothing from Hitachi)

There are in the PLL section of a RANGER RCI2950 tranceiver and
I want to understand how does it work. I've made some deductions
but I don't think they're all right.

Thanks for any kind of help.

Here are the dimensions for the Wilkinson Hybrid for 88-108 Mhz. Its
center frequency is 97.49 Mhz. You will need two lengths of PTFE
(Teflon) 75 ohm coaxial cable suitable for the power level being used.
Do not use anything other PTFE cable. The length is 54.4 centimeters.
connect in a V configuration. For the splitter to drive the two amps,
at one end of the cables conncect the two center conductors together and
the shieldst to ground, this is your input. At the other end of the two
cable are your two output ports to the two amps. Shields are connected
to ground with the two center conductor becoming the two output ports. A
100 ohm non-inductive resistor is connected between the two output
ports. It has to have a dissipation equal to 1/2 of the applied power.
For the combiner use the above configuration but the output ports become
the input ports for the two amps and the input port becomes the output
port. You will need a non-inductive resistor with a 150 watt capability,
these are made especially for RF, contact Richardson Electronics for them.

From: "Gary P. Fiber" <gfiber@halcyon.com>
Subject: ICOM IC-2SAT HELP!?

>1) does this radio have a tone burst for reapeter use ,if so how
>is it operated?

On the 2SAT, 1750 Hz burst could be added if the serial number was below
about 9500, also the minimum offset tuning step size needed to be 25 kHz.
Here you would need to convert the radio to a european version and install
2 SMD resisotrs. After S/N 9500 or so the offset tuning was made
adjustable and the 12.5kHz tuning step was removed, also so was the ability
to have a 1750 hz tone burst. The reason was to free enough memory in the
CPU to have the adjustable offset tuning steps rather than the original
fixed 25 khz tuning in the earlier model 2SAT radios.

>2) my radio seems to have rx 100-200 Mhz and tx 140-150Mhz
>but the disply will read 0-1300 Mhz. does this mean it can
>be made to receive from 0-1300 Mhz if so how?

The radio will actually receive from 110 to 136 aircraft A.M. and 136 to
174 Mhz F.M. Signals above or below this range are usually overloads or

images. The tuning ability never stopped in the CPU program, how ever the VCO never had the kind of range the frequency readout would report.

According to my Motorola RF Device Data handbook the MRF327 is an 80W 100-500MHz controlled Q broadband RF power transistor. Guaranteed 80W output over 225-400MHz, min gain 7.3dB at 400MHz. Now what you would do with five identical boards like that is a different question but they are

VHF broadband finals and the 8851 is almost certainly a date code
indicating that they were manufactured in about May 1988.
Hope this helps.

From: rst@tetrault.com (Bob T.)
Subject: Need ID: Motorola final/ MRF327-8851

MRF327's are 80W broadband controlled Q transistors for frequencies
100-500 MHz with guaranteed 400Mhz 28VDC performance. The 8851 number is
the 51st week of 1988 when they were built. Call your local motorola
office and ask for the data sheet; they shouldn't balk at sending it out,
just don't tell them the surplus/curiousity story...

Another gentleman described the device itself, and I'll add that the
"8851" means the part was manufactured in 1988. The "51" could mean
Day 51 or May 1. These codes vary, tho I'll bet the military has a
standard, which I don't know.

Fersure don't miss Motorola's Web site:

http://motserv.indirect.com/

There is a HUGE amount of information there, including a lot of nice
downloadable data sheets in Adobe Acrobat format.

Good luck with that rig.

From: kmiller@airmail.net (Kerry W. Miller)
Subject: Schematics going to a web page

Hello again, guys!

Well, I asked before I posted the schematic and got many good
suggestions about where/how to post the schematics. Now that I've
posted the first one, everyone has been very helpful except for a few
flames from those who didn't appreciate me using up the bandwidth in
the newsgroup. I knew it might be a hardship on some folks, that's
why I asked first! Wish they'd have said something before I did it!

To accomodate those who don't want them on the newsgroup, I'll be
sending them to a gentleman who offered to put them on his QRP web
page. When I finish cleaning up the scans, I'll send him the files
and you can find them there when he has time to upload them.

If there is anyone who doesn't have access to a web browser or can't
get to them, let me know and I'll put the drawings into one big zip

file and send them via email. The whole lot of them will be around
250Kb, so it won't be unbearable.

Hope this works, I'm sending this note with Eudora and I've never
tried making a mailing list before! I'll drop a note on the newsgroup
for anybody who misses it. Thanks for your patience and suggestions.

The web page to watch belongs to:

John R. Cunliffe N2NEP
cunliffe@frontiernet.net
http://www.frontiernet.net/~cunliffe

Keep an eye out for it, maybe the schematics will appear there in the
next week or so. Make a bookmark!

>
>I'm seeing conflicting information on the technical specifications (i.e., >temperature coefficient) of NP0 and C0G capacitors. Some sources >indicate they're identical; others show slight percentage differences >between the two.

Hi Paul,

Since no one else has come forward, I'll offer my two cents worth. NPO stands for Negative-Positive-Zero. COG is a type of ceramic dielectric, much as Z5U and X7R are. COG is considered to be an NPO, whereas Z5U and X7R capacitors vary radically with temperature.

I'm not aware of a standard, although there could be one. If your application is critical it may be wise to consult the manufacturer's data sheets for exact specifications on a particular device. Manufacturing processes also affect drift characteristics so similar capacitors from different manufacturers, using the same dielectric material, while close, will display predictably different drift characteristics.

Hope this is of some help.

Regards,
Bill Sorsby, N5BU

1179. DS-1A (DC-DC converter for Kenwood) question

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-14 00:00:00 UTC
From: cnc23a@b4pph13e.bnr.ca
Message-ID: <4ft09j$ias@crchh327.rich.bnr.ca>
Source record: 107305
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

I have a Kenwood TS-820S that I would like to run off battery in
cases of emergency. And as a (good ?) homebrew project, I thought
I could emulate the offering from the manufacturer. Problem is,
the information in the back of the service manual is sufficently
ambigeous enough that I have a few questions.

Is the transformer shown part of the DC-DC converter kit, or is
it the one already in the radio, with the barrier strip that already
has the matching color coded wires ?

The drawing shows the same connector as used for AC input, but wired
for DC, then another "power connector" thet does not appear to match
the previous which interrconnects with the barrier strip. How exactly
is the power (DC) connected into the system ?

Any other hints/explainations on this 'project' would be welcomed.

Thanks..

I just bought an Amp Supply LK500 linear amp, running a pair of 3-500 tubes, and immediately blew a leg out of the HV rectifier stack. These diodes are listed as 1N5408 diodes, and there are 4 diodes in each leg of a full wave bridge. I have no idea what the ratings are on these diodes, and would appreciate info from someone who might have a reference manual. I amd also unaware of availability of these diodes at this point in time, and haven't figured out whether to replace the bad string, assuming I can locate exact replacements, or just go ahead and replace the entire string with some diodes having higher ratings than what it originally came with. All help and comments appreciated!

Thanks. My two concerns with this design are fast lock times with variable
step sizes and low phase noise once lock has been acheived.

Cheers,
David

1184. FS PTS 160, 100KHz to 160MHz 1Hz resolution DAS synthesizer.

Newsgroup: rec.radio.amateur.homebrew

I have a mint PTS160 frequency Synthesizer by Programmed Test Sources.
It generates carriers from 100 KHz to 160 MHz in 1 Hz steps. The unit uses
Direct Analog Synthesis and can switch frequencies in extremely short times.
Power is adjustable from the front panel up to around 15dBm. Unit is calibrated
and within 1Hz of WWV. This unit sells new from PTS for over $7000. Asking
$1200. OBO. Unit has TCXO, GPIB, Rack mount and other options.

Gary,

Tried to send you email but your host says you don't exist.

The 1N5408 is rated for 1000V PIV, 3.0A, 125A surge, 1.0 Vf. Digi-Key has them at 10 for $3.36.

I'd replace the whole string.

I don't think you'll find a beefier diode in that same package (DO-201AD). If you have enough room to work and can handle a slightly larger package, something like a Motorola MR760 which is rated for 6A might be a decent upgrade. I don't think I've seen diodes in small packages like you will need that have PIV's larger than 1000V, but they're probably out there somewhere.

I've seen a blowout as you describe because of RF-related problems elsewhere causing a lot of radiation inside the cabinet of the amplifier. Just a quick blue flash and adios power supply. A friend of mine had the same thing happen with a single 3-500 amp sold by AEA (OEM Vectronics).

Synergy Microwave Corp also makes them. Talk to Electronic Development Sales. Phone 02-418-6999 and ask for Earle Goodwin or Henry Loh. Small quantities OK. About $AU80 or thereabouts. Model VCO-x-1000 or VFC-x-1000 where x=P or S. Both 1-2GHz.
P=Pin out, S=Surface mount. Both models have the same elect. specs. Mech details vary slightly.

The folks in rec.crafts.metalworking are facing this same problem.
I believe you'll find that unless the Postscript file uses only
the basic line drawing primitives, information is lost and you won't
be able to reconstruct a CAD file from the Postscript file.

Postscript is a printer language, IE it describes a bitmap in
terms of a set of descriptive primitives, and isn't generally
a good geometric object language suitable for CAD.

About 2 years ago there was a very detailed description of a
homebuilt GPS Rx in the german journal UKW-Berichte.
It went over several issues and if I remember correctly there were
detailed schematics.
The author was a very wellknown Yougoslawian amateur.
The article was in the german language.
Hope this helps

Dietrich DJ1VA

NB.: The rx was also suitable for GLONASS.

1194. ANCIENT W.M Welch Oscilliscope, Info needed!!!

ANCIENT W.M Welch Oscilliscope, Info needed!!!

Hello.

I've been posting q's about GPS, haven't found too much info.

HOWEVER!!!
I recently acquired a Cathode Ray Oscilliscope from my Physics teacher,
with a little coaxing, and I have no clue how to make it run again. It has
vacuum tubes and a huge CRT projector. It's a work of art, however it
looks like it was soldered together by a two year old.

Technical information.

It's a W.M. Welch CROscilliscope, 115 volts, 50-60 cycles, 35 watts.
CRT projector is model... Phillips JAN-CNY-5cpl
Vacuum tubes:
RCA 2x2-879
RCA 6x4
CBS 6CG7
Sylvania 6AU6 (two of these)

There are two huge capacitors
Solar CP70E 1FH504K
1500WVDC .5 mFd

Asst. large resistors.

Ancient transformers.

My best estimates are that it's 40's vintage.
I want to get this thing to work.
If anyone knows of technical data, and replacement parts for one of these,
Please let me know.

Thanx, Dave.

: I have been trying to do the same with my KODAK lazer printer.
: Generally it is black enough now I have set it darker from the slider
: bar in printer setup options in windows 3.1. although the acetate film

My Brother HL-8V (HPIII compatible, uses the Canon SX engine - paper
tray in front, output on the top) has a knob inside to adjust "darkness"
as well, and it really makes quite a difference (in output, I
haven't tried making PC boards yet). If your printer looks similar to an
HPIII it probably has this control as well. Open the printer as if
you were going to change the toner cartridge, and the knob is on the
front left corner of the open space.

: I am using goes a bit crinckly through the heated rollers.
: Have you any suggestions as to software for making PCB layouts?

Corel Draw works nicely if you are doing it by hand, or if you have an
old pattern not suitable form directly photocopying onto acetate,
you can scan it, import it into Corel, and then draw the traces over top
(trace the scanned version). When you're done tracing it, remove the
bitmap from the background and you will have nice cleaned up artwork.
The nice thing about Corel (as opposed to some generic CAD program) is
the ease of doing curved lines, and making closed shapes which you can
fill solid black. Alternatively, you could take the scanned version into
Photoshop, tweak the brightness and contrast to get rid of smudges and
inconsistency, use the line tool, paint brushes, etc. to clean up edges
and light areas, and print that, but Photoshop would be one of the worst
choices for creating a layout from scratch.

If you're going to design a circuit, there are some schematic capture
and PC board layout packages. I got Chipmunk and some other package,
both for Linux, and they appear quite nice and easy to work with but
I haven't done any real work with them yet. My conclusion after designing
one board with a really ancient version of PCAD that I picked up at a
hamfest is that doing a schematic first isn't worthwhile unless you need
it for documentation, or can afford one of the nice ($1000+) design programs
that has a worthwhile router. PCAD did such a lousy job routing that I
ended up doing layout from scratch anyway, and mentally verifying the operation

of the circuit based on the pc board layout rather than the schematic.

: I believe that if you dilute it well you may spray it on your yard and it will do a
: nice job of greening it up(in warm weather, of course). Ferric cloride is acidic
: but not a strongly so as, say hydrogen cloride(muriatic acid), since iron does not
: hold on to its outer electrons as well(being large) as hydrogen, and so ionizes much
: more easily. Iron plays an important role in the manufacture of clorophyll and this,
: of course makes the grass green.

Two comments: if it's spent, after etching copper-clad board, the copper sure won't help the plant life much. And if it's not used, the Fe+3 is a fairly strong oxidant (etches copper after all), and may not be as good for plants as Fe+2.

Second, you can't dissolve very much ferric ion in neutral water! The solubility product of ferric hydroxide is something like 10^-36, so if you want one molar ferric ion, plan on getting the hydroxide down to about 10^-12, which means the hydrogen ion must be 10^-2, or pH=2 or less. In other words, to get ferric chloride to dissolve appreciably in water, you must make the water acidic. Otherwise you get ferric hydroxide precipitate, brown "glop". In fact, by the act of precipitating, it leaves behind hydrogen ion, so whether you add acid to get everything to dissolve, or just remove hydroxide by letting Fe(OH)3 precipitate, you've made hydrochloric acid solution. It's not terribly strong, but do treat it with some respect.

1198. 'Memory keyer - Public domain code'

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-15 00:00:00 UTC
From: ed@fore.com
Message-ID: <4fvojr$1fp@baleen.fore.com>
Source record: 107236

Does anybody know of a microcontroller based keyer with public domain
software? I have FTP'd, and searched, and archied, and webbed, and havent
found one yet. Perhaps it doesent exist.

I recall a while back there were a lot of posts complaining about a cpu
Super Keyer construction article published recently in QST, not having source
code. From what I understand, the only way to build this keyer was with his
preprogrammed $50 chip.

Well... I pose an idea...

Pool a list of desired features, get a group of geeks together via internet,
and group write and post the source code, and design and build a public
domain keyer... and then make a group article for QST.

Sound plausable, or am I asking for a democracy in the land of chaos?

Perhaps we could have code for several types of Microcontrollers.

My personal MPU of choice is the motorola 68hc11, why is that you ask?
Low cost - under $20 bucks each. (I already have some)
EEPROM 512 bytes, ram 256 bytes, on board serial and parallel and A>D ports.
It can be programmed via its own serial port WITHOUT A SPECIAL PROGRAMMER!
The motorola compiler software is available via bbs and internet to run on a PC.
I like many others learned 6800 on a heathkit trainer 10+ years ago and am
quite comfortable with its instruction set.
The design could be easily be ported to 6800, 68x711,811 or whatever.
Perhaps there is some guru who could port the final design over to RISC for PIC.

Features/functions...

Iambic operation, single or dual paddle.
Single striaght key operation. (How? input requested)
Adjustable weight, speed and spacing. (Pots to analog input channels? input
requested)
Multiple memorys - push button selection.
(several discrete buttons, or up/down buttons and status leds? input requested)
TX relay control for older tube type rigs that shorten first character while
the tx/rx relay closes. Prevents relay from opening until EOM or SK is sent.
Perhaps an SK button?

Now is your chance to have some input into a new keyer design, one that you
can really build and program yourself!

Send your thoughts to Ed@fore.com

Recently, I was so impressed with Adobe's Acrobat PDF (Portable Document File) format, that I bought 300 shares of their stock. I also purchased their $125 Adobe Exchange for win that produces .pdf's from any app that can print to a windows printer. Portable means all platforms; Windows, Macs, Unix.

Adobe has a free download of Acroread, which is a subset of the Exchange SW that allows reading and printing *.pdf's.

I discovered Acrobat by visiting the Maxim Integrated Products site (search on maxim). They have a link to the free reader download. I downloaded a 10 page Maxim data sheet in 45 seconds at 14.4 K. I was astounded by the quality and detail of the line art and the tiny fonts. It took 4 minutes to print on an old HP laser III without Postscript capability. May be much faster with Postscript printers.

I have used Exchange on a 255K WordPerfect document containing several Acad generated line dwgs, to produce a 110K PDF that prints with no perceptible degradation.

I see now that Motorola is also using Acrobat PDF, and a CD sampler from Adobe implies that the Dept of Defense is standardizing on PDF and using the Adobe Capture product to archive all DOD legacy paper

documents.

The CD sampler contains the complete works of Shakespeare, a complete issue of the London Herald, several informative videos and lots more. Adobe sent it to me free and that is where I discovered the $125 special offer for Exchange.

My Adobe stock is doing very well.

The mod is easy. This will give you 137-174mhz and 410-470mhz Tx/Rx.

1. disconnect power and antenna (like, you would'nt of done it already.)
2. open up the case by removing the screws and gently removing the cover and unpluging the speaker.
3. locate and CUT the GREEN WIRE on the CONTROL BOARD (the vertical board behind the control panel.
4. reassemble the radio.
5. RESET THE MICROPROCESSOR (so much for the memory!)

(press and hold [D/M] & [REV] & [ENT] & turn the power on (got enough fingers?).

(turn off the radio).

(press and hold [SCAN] & [HOME] & turn on the radio (extended RX mod).

Tha, Tha, Tha, That's All Folks!

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet mailing list counterparts and complements. It is intended to serve as a guide for the new reader on what to find where. Questions and comments may be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October 1994 to add the discussion of non-Usenet mailing lists and streamline most of the history discussion, and to change the moderator information for rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions were held on the mailing list, and sent to the mailboxes of those who had signed up for it. When the Usenet software was created, and net news as we now know it was developed, a newsgroup was created for hams: net.ham-radio. The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became progressively higher. First one by one, and then as part of two reorganizations, what was once one group became many. In the process, developments elsewhere on the net were reflected in the groups as they were created, most notably the change to place all of the ham radio groups in one hierarchy.

The collection of newsgroups continues to grow as more people join the net, and as more topics of discussion gain volume, I expect to see more groups be created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the notable exception being rec.radio.swap. There are also a few mailing lists that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them, and not to the groups that aren't. The whole idea of having different

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

Hi !
Since I'm planning a 23 cm repeater, and I am not in the USA (!)
I was thinking about buiding it on my own.
And using an atomic reference (of WWW kind) to lock it.
Since I want to be able to choose the input and output frequencies,
I need something tuneable. I thought about comb filter with three
digits, the middle one being tuned by a varicap (or PIN diode).
Does anybody have any experience in this field ?
Should I use a YIG instead ?
Another form of filter ?
What noise can I expect from such a system ?

I thank you in advance for any suggestion

Hello all

Has anyone ever done any work to quiet down the ignition system (spark impulse noise) in a gasoline powered vehicle?? I wonder if one could use large ferrite beads to choke off the spectrum of the spark from radiating off the wire at the frequencies of interest. 1 mhz and above? I have done a lot of grounding , and am using resistor plugs and wires.. Are there any shielded wire kits out there?

Last year I tried using COG capacitors in a VFO design. My local supplier had commented that COG is the same as NPO. In my case, I found that the resulting drift was *much* worse than the assorted NPO capacitors I had been using.

Of course, your mileage may vary....

>capacitors vary radically with temperature.

I think that some of the negative experiences that I have had with drift
and COG capacitors could be due in part to their small size (I have a very
difficult time even reading the markings on the tiny little things). The
NPOs that I have dealt with are quite large in comparison to the *very* small
size of the NPOs.

With such a small size, any RF heating of the part will cause a significantly
higher temperature rise in a very small part than a much larger one. This
could have accounted for the effect I was seeing.

There are two catches: Although copper salts are relatively non-toxic
for humans, they are highly toxic for bacteria etc. and therefore
enviromentally harmfull. Also the ferric chloride is very aggressive,
during hydrolysis it releases substantial amounts of hydrochloric acid.

You have been warned. 73, Moritz DL5UH

Source record: 107237

What is the lowest typical S/N ratio which can be handled by a
PLL as a FM demodulator?

Do PLL's reject signals which are out of the desired frequency
range? Or must a filter precede the PLL to select only wanted signals?

If they have a lock on a signal will they be likely to jump to
another signal if it is within the desired band? Assume for example
that there are two unmodulated carriers at 262 and 263 KHz coming into
the PLL; will the PLL prefer the signal it's locked on, or tend to
capture the other?

Hello Paul:

I have had good success with passing the ignition cables through some Snap-On Chokes. However, you will have to use a large number of them because, if your vehicle is like my Ford Ranger, there is not enough slack in the ignition cables to loop them through (I really wouldn't care to try it anyways).

I wish you luck

1212. Information on equipment sought by new Tech

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-16 00:00:00 UTC
From: tomz@premier1.net
Message-ID: <DMuJuB.GLH@data-io.com>
Source record: 107240
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.policy,rec.radio.amateur.space

Hi,
I am going to be taking my Tech tests on Saturday (2/17) and am now starting to look in to what type of radios to get. I plan to put a 2M Mobile in my truck and get a more substantial base for home.

For home I'm looking into Base Multiband / Multimode Transceivers and trying to decide what will be my best bet. I was thinking of one that would cover at least 2M and perhaps 70cm. I am interested in working into Satellite and EME as well as FM and perhaps some local CW, 12V operation would be a plus but not a major requirement. I do plan on upgrading to at least General with in the next year and expanding also into some HF as well. So I would want to take that into consideration as well. possibly using Transverters get to the higher freqs for satellite and EME and going with a more basic UHF/VHF base unit.

For the mobile unit I was thinking of a rather simple 2M unit for repeater and simplex FM. I live in a rather remote area in the western foothills of the Cascades so I think one of the higher output power units would be in order. I was considering picking up one of the new Radio Shack units. As far as I can tell it has most everything I am looking for at a reasonable price. From the cross talk I have seen on the net and the write up in CQ (VHF) it seems to be a good choice.

I would like to take advantage of the wealth of experience of those out here on the net and get some input from you as to what you think. Suggestions on equipment to get or avoid as well as things to look for or useless features to not even consider. For me price, value and reliability are important, I have a modest but hopefully adequate amount set aside for starting up and want to use it wisely. The Base unit I'll be looking for used at up coming Ham fests so any information about current or older equipment would be helpful. I was thinking of picking up the Mobil new (if it is in or around the same price range as the Radio Shack unit) but am vary open to suggestions. I would also welcome comment on other accessory gear that you feel would be useful as well as thoughts on band selection (pros and cons of the diffrent amature bands) or what ever info. you would like to pass on to a newbie like myself. I know there are lots of books and other sources around and would not mind pointers to the better source like that, but I am primarily looking for personal insights and experience.

Thanks
TZ

Hello:

It never fails, you keep a magazine for years and one day decide you should toss it out. Within seconds of the garbage man taking it away, you NEED an article from it!!!

I'm looking for an article on building a handheld D.F. antenna with a small doppler circuit on the handle. This particular one looked like a bow tie antenna on a short handle with a 9vdc battery and PCB doppler circuit attached. I can't remeber which mag it was in, but it was a few years old.

If you have the article or a similar circuit, can you PLEASE contact me and I'll pay for costs to get a copy.

If you wish, you could fax it to me, call my voice phone number and I'll arrange for the fax to be collect.

You might want to get the book "Radio Frequency Transistors, Principles and Practical Applications" by Norm Dye and Helge Granberg of Motorola. Chapter 11, Power Splitting And Combining, may prove useful. The book is published by Butterworth-Heineman, 80 Montvale Avenue, Stoneham MA USA. Closer to home, you might try Linacre House, Jordan Hill, Oxford OX2 8DP, United Kingdom. The ISBN number is 0-7506-9059-3. (Listed at $49.95 U.S.)

Is anyone familiar with the low-power AM broadcast transmitter(s) used by Airports, DMV's real estate agents, or drive-in theatres to broadcast local site-specific information to car radios?

I know, for example, that some real estate outfit puts 'em in houses for sale, and you can hear the whole lowdown on the house by tuning in on your car radio. Some airports do the same thing to give local information on parking and rental cars.

Is some sort of special license required? Who makes the hardware? Is it expensive? Any guidance or direction would be appreciated. Please email, though, my newsreader is less than reliable.

I haven't had any experience with them, but what about the connectors that
are designed to be connected/disconnected underwater? I'd guess they may
do a good job protecting both the "plug" and the "socket" ends from
contact.

Exactly speaking, PostScript is a programing language having a lot
of language elements suitable for various tasks, but especially
for graphics. There are language elements for bitmaps as well as
for vectors, circles of fonts. Have a look on the PostScript FAQ.

I am trying to determine if a CD-ROM or Floppy Disk exists listing all
Vacuum Tubes. It would be preferable if the program had a database of
individual tube specifications but a simple listing would be
satisfactory. Any help will be appreciated.

I bonded my entire vehicle a few years back. The interference from ignition dropped from S-9 to S-2. Follow thw suggestions in the Radio Amateurs Handbook for mobile installiations. Most police vehicles use the same type of body panel bonding where all of the panels are connected with braid. it does work quite well. Also you might want to install some 0.01 uf disc ceramic caps across the heater motor leads and wiper motor leads. This helped quiet them down too.

Hi,
First I would be sure to get a unit that does both UHF/VHF. There are now more UHF repeaters in some states (Texas for instance) than VHF! The Yaesu 5100 is a good choice as are some of the kenwood, icom, and alinco models. I like the one that allow for 2 V's or 2 U's as well as a V and a U at same time.. so look for that.

For satellite work you need All mode rigs (CW/SSB).. they are considerably more expensive than the FM variety. You can use transverters from an HF rig, but you will lose features like auto doppler shift correction etc. AND if you want to work some of the satellites that have UHF/VHF/HF capabilities it becomes difficult with the transverters in line.. but not impossible.

Get a good FM Dual bander... learn about the hobby from a local club, see if others are into satellites and find out what works for them. Grab the general/advanced and then have fun!!

73 hope this helped a bit.. perhaps others will comment.

>ka8ddz

Tim,
Thanks, but I'll save you the "flame job" that I got for asking
and then posting the first one! I knew it was poor netiquette to post
binaries on a non-binary news group, but after I asked and got several
positive responses, I did it with the first and smallest one to give
it a try. Apparently there is quite a bit of lag time on some
servers, I got negative responses after I posted the file.
The problem with binaries is that several folks apparently get
this newsgroup through a mailing list, therefore they get everything
that gets posted whether they want it or not. A binary file takes too
much time for them to download, especially if they are paying by the
minute.
I posted the short one first to give it a try, but now have found
a better way. All of the schematics will be on John Cunliffe's web
page at:

www.frontiernet.net/~cunliffe

He'll put them up as soon as he gets them. I already sent him the
first two files. This way, the guys who get the newsgroup from a list
won't have to put up with it. When he gets all the files posted, I'll
drop a note on here.

Thanks for the help, but the guys are right, it really isn't the best
way to do it, it was just the only way I had at the time!

You wouldn't want to post it here, because it's generally considered
to be poor USENET practice - many people pay for their news/mail
feeds, and don't particularly like paying for massive posts in discussion
groups. Not to mention that the ignorant poster will quite likely
be mail-bombed. :-)

The *PROPER* way is to post a short note indicating the FTP site where
the schematic can be retrieved, or the address of a web page where it
can be viewed. As it happens, there is a QRP mailing list at
lehigh.edu that also has an FTP site full of QRP-related material.
That would be a fine place to put it.

David is quite right, images and binaries have no place on a newsgroup like this. The schematics should be put on a server somewhere, so that they can be downloaded using ftp. A short periodic posting could then be made to inform people where they are, or a mention made in the group's FAQ. This way, they are always available, people know where they are, and bandwidth isn't wasted distributing them to people who don't want them. This is simply good "netiquette", and is probably in this group's charter, that was promulgated when it was formed, and should also be in the FAQ, if one exists.

Buy "The CCD Camera Cookbook" by Veikko Kanto, KB7UCZ, and John Munger, N7WBQ.
The publisher is Willmann-Bell, Box 35025, Richmond, VA 23235, (804) 320-7016.

This will take you through theory to construction and operation of a CCD
camera. The book includes software for trouble shooting and image processing.
I'm not sure of the cost, but I believe it's under $20.

Have fun.

That's not a bad idea in some situations. Generally though, you want the loop filter to be as wide as possible in order to track out the inherent noise of your VCO. Sometimes you want to FM the VCO by adding an audio signal to the output of the loop filter - then, a narrower loop filter won't track out your FM signal.

Typically, the clock-feedthrough of a SCF will tend to cause nasty sidelobes on your VCO unless you place additional RC filters in the circuit. Essentially, the requirements for the loop filter are easy to achieve with a simple 2nd order circuit. SCFs really don't add anything to the performance.

> Just a few thoughts and questions. BTW, anyone have a good VCO design for
> 60.7 to 64.7 MHz? :)

You might want to check out Motorola App Note AN980 and the data sheet for the MC3362 for some tips on such things. The MC3362 has a built-in oscillator and varactor diode which work up to 180 MHz, and I have seen 40m designs using it as well.

Ill reference Feb 1996 73 magazine, article "Basic Packet Modem".
Doesn't seem to difficult to replicate and the price sure beats
whats available commercially. (if all you want is the BASIC packet).

Sometime ago, I built a baycom for my C-64. The questions I have,

1. Can this C-64 baycom interface be modified to run on an IBM?

2. If it can be changed, what software could be used (Procomm
perhaps)?

3. Has anyone sucessfully done what I am looking for?

Thanks for stopping and looking in.

Hi Steve,

I'll bet you are looking for the "Handi-Finder", which was described in QST, May, 1993, pg. 35. This circuit was not really a doppler design, but one of the "time difference of arrival" designs. I don't have a fax at home, and cannot use the work fax for personal use (even collect), but maybe one of the other folks reading this can help. If all else fails, I CAN mail you a copy. Let me know.

: Thanx

I suggest that you don't bother to build your own. They look really complicated, full of proprietary software. I think GPS is fascinating but you will end up with a whole tabletop full of stuff to emulate what goes on in a pocket sized case.

I think you are best off saving your money do buy one and finding interesting things to do with it.

There have been articles in 73 Amateur Radio Today and QST about things to do with store-bough GPSs, but they dont build them for the same reason they don't build their own handi-talkies.

Paulc,
You did not mention the age or type of vehicle. These are important factors since different models manifest there noise in different ways. One of the biggest problems in vehicles and boats are the alternators. A good preventitive maintenance item is to take your vehicle to an electrical shop and have them rebuild it. If that doesn't work then you might need an alternator filter. The marine types work best don't waste your money on the radio shack units. Install the filter as close to the output of the alternator as possible. The caps across all small motors and the bonding of body panels works good too.

Wiliam,

The vehicle I am driving is a Volkswagen Vanagon, 1984 with electronic
ignition and fuel injection. The noise is coming from the ignition
system it is very easy to determinr when each plug fires. I may try
bonding parts of the vehicle although there are not a lot of
unconnected parts. I could try the doors and rear gate .

Thanks alot PaulC

I've looked into this also for my TS-820. The box that connects
to the TS-820 that allows DC operation only contains a two resistors
and two mega transistors.

The transistors are no longer in production, but the equivalent
is ZN4049, PNP germanium, 60A, 45V, TO-36, NTE28 at the tune
of $45 each. Thats $90 a pair. Not a pretty picture.

I think it would be more feasible to buy a DC to AC converter for
your cigarette lighter plug and drive the TS-820 with 120VAC.

I would be interested in anyones experience doing this.

>Hi!

Sure you can build one....it's been done by Madjaz Vidmar in I think
is called VHF-Communications, a German magazine and as far as I
know also available in the USA....
I'm sure that building a trx for example for HF which is good, is
more expensive than buying one, so the price is not always an
argument.
I'm at my qrl here, if someone wants to know exactly which VHF-COMM
decribes the GPS-system, just let me know.

1275. ### KISS on a Baycom?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-19 00:00:00 UTC
From: edwint@greenie.com
Message-ID: <312852fb.1d2@greenie.com>
Source record: 107103

Hello people,

I've recently taken an interest in working tcp/ip over
packet, and it seems a little difficult to do that
with my homebrewed baycom-style packet modem.

Anyway, I've been considered porting over to a varient
of unix, and it seems I would need a TNC which supports
KISS (that'd mean my baycom would have to be scrapped).

Since cost is a rather high consideration for me, I'd like
to know if it's possible to homebrew a KISS interface for
a baycom-style packet modem? The idea doesn't seem impossible,
could someone point me in the right direction to work on
such a project?

>pwr.
>73,
>Kerry

No offense Kerry, but that must have been a VERY special 77 two holer or the guy was BS'ing you. For example, I can find a lot of old Pontiac GTO owners that claim their cars run 11's! ;-) If that ETO was really doing 8 k out, the fire would have been in the amplifier! Maybe with the feedpoint arcing the meter said 8 kW, but 4 or 5 kW of it must have been reflected power!

77 two holers only run around 3-4 kW out (even with the bigger transformer)! 160 is one of the worst bands, where they only do around 3 kW or so out. Even at that power, the HV is down from 4000 volts no load to 3 kV!!!!

The plate choke is too small and the tank is too inefficient on 160, there is no input matching (just a parallel L/C circuit), and the power supply is WAY too weak. Even if you fixed all of that, the grids of the 8877's would pop like last week's Mexican dinner if each 8877 was pushed past 3 kW. With a big external plate supply and a big exciter a 77 owner is VERY lucky to see 5 kW out.

It takes a lot more than a tiny little girly whimp like an 8877 (or a even a pair of those little sissies) to do 8 kW! It takes a man sized amp with some real hair under it's arms.

Alas, older VWs had chronic ignition noise problems. Fortunately
there is a cure. VW engines are used in homebuilt aircraft, and
there is a *fully shielded* ignition kit available for the VW
engine. Check at the airport.

Hi Ed, sounds like an interesting project, and maybe something like this might get this group doing more that talking (spice things up a little). Its been getting a little boring here, and it is a homebrew group.

As for the processor, what is the power requirements of the HC11? I would think you would want to keep the power low, and would also think that the 6805 family might have some lower powered versions available. If I remember right, some of that family can also program themselves by a simple connection to a PROM.

I don't know if I can spend much time on it right now, but keep me informed if you get into a mail-list mode.

>with this part. THe jitter is down to internal jitter of VCO (Claimed).

The problem with a switched capacitor PLL loop filter is that the
residual sampling noise of the filter could introduce additional
modulation sidebands in the VCO. This can be reduced by using an
RC low pass filter following the switched capacitor filter with a
corner much higher than the loop filter corner but lower than the
filter sample rate. The important question is "what is the application?".

A PLL used for frequency synthesis will be much more stringent than
a PLL used for clock recovery on a data signal or FM demodulation.
If you have modulation sidebands out 1MHz from the synthesizer
frequency that are -60dBc, that may not mean snot to a data recovery
circuit but could wreak havoc in a broadbanded radio transmitter.

I'm not familiar with LTC Design Note 7, but I'd guess they're
using the 4046 in some application other than a radio transmitter
or receiver local oscillator.

I've looked into this for my TS-520SE. The DC version TS-520S
(or did I reverse the two names?) has an added heatsink on the back
with two switching transistors, wired to a terminal strip in the
rig. The power transformer is different, however. It has an added
winding to serve as a low voltage primary, switched by the transistors.
To convert to 12V DC in you would have to change the transformer
and add the heat sink/transistors on the back.

Tom,
Hi! It really will do it, but not for long. The 8kw was on a
PEP meter, not a "real" meter. The 8877 won't last long at that rate,
but this guy has more money than sense anyway. He has a wall full of
OO cards, collects them like QSLs!
73,
Kerry
PS Yep, he's full of it, but I saw the meter this time, I thought he
was lying too, had to go see it. Does that make me an accessory?

1293. Tunnel diodes: are they any good? If so, any circuits out there?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-19 00:00:00 UTC
From: tiemann@spot.Colorado.EDU
Message-ID: <4gb2jb$jql@peabody.colorado.edu>
Source record: 107121

I've inherited some tunnel diodes, and I've heard them mentioned along with other things to produce microwaves. However, no issue of QST I have (since 1990) nor the ARRL UHF/microwave book actually presents any circuits to make them do something specific, with component values, etc. Could someone point me to such sources? I'm interested in 5.7, 10, and 24 GHz at the moments, but if they go higher...

If they have gone wayward for a reason, "the spark transmitters of the microwaves," say, then I'd like to hear about that too. Nothing I have gives them more than a line or two of "Tunnel diodes can also be used to generate microwaves."

Thanks,

Bruce, N6URH

I have several restoration in progress and need parts. Do you have any
old telegraph keys or bugs lying in around. I would like to buy what you
have for parts. Would also be interested in any servicable keys that you
have. Check out my home page for a list of duplicate keys that I have
for trade.

1297. How to make a simple Hi-Q loop

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-20 00:00:00 UTC
From: Peter Shintani <shintani@tv.sony.co.jp>
Message-ID: <4gb4c3$qeb@oskgw.osk.sony.co.jp>
Source record: 107125

Hi:
I decided to throw away some efficiency for the sake of simplicity.
Most HF hi-Q loop antenna are made in the shape of an octagon since
this approximates a circle quite well. However, there are many 45
degree elbow joints which can cause the resistance to increase and thus
reduce efficiency. Furthermore the use of a trombone capacitor for
tuning is "neat" but is places hardware inside the loop and is difficult to
align for smooth operation.
I designed and built a square loop. Cut a 10 foot piece of 3/4" copper
pipe into four equal lengths. Use two 90 degree elbows to join three of the
pieces into a square. Attach a "T" fitting to the unattached open ends. Take the
remaining fourth piece of pipe, cut about an inch off of it, and then cut it in half, so
that
it is about 1.25 ft long.
There are plastic pipe inline joint meant for 1/2" ID
plastic pipe. 1/2' plastic pipe OD is very close to the OD of 3/4"
copper pipe. Ream the inside ID out so that it makes
a tight friction fit over the 3/4" copper pipe piece that is about 1.25 ft long.
Slip the plastic joint over one of the 1.25 ft long piece. Fit a 1.25 ft piece
into a "T" fitting, and do the similar to the other side. Finally, tightend the
plastic joint to make a rigid square. No alignment problems.
Sweat solder the T fittings and 90 degree elbows. Make sure to push the plastic joint
away from the side being soldered, it might be deformed from the heat of soldering.

Buy and cut a +2.5 ft length of 1/2" pipe
and solder some nuts into the ends, cover with heat shrink tubing. Slide
the 1/2" heat shrink covered pipe into the loop through the "T" fittings to
make a variable capacitor. Use a threaded rod to move the 1/2" pipe with a low
rpm motor.

A gamma match is used to match the coax to the loop, it should be centered opposite
the plastic joint, and it's lenth should be about 1/4 the length of the main loop.
I used a ferrite bead balun but I haven't confirmed if it hurts or helps. The piece of
RG-58, I had already had 70 beads on it from a previous project.

As is the antenna tunes from 10~30 MHz. If a vacum variable is used place of the
coaxial capacitor, the distributed capacitance affect is reduced so with a 5~200pF
unit, the tunning range is from 6.8~30 MHz.

Good luck and I welcome all comments.

Peter

1298. List Of Stamp Applications [960220]

```

Contents

1.0 What is BASIC Stamp ?
1.1 What is L.O.S.A all about ?
1.2 How can I contribute to this list ?
1.3 Where could I find L.O.S.A ?
1.4 List of contributions.
1.5 Credits and other things.

1.0 What is BASIC Stamp ?

This is being written for people who have no idea of what a BASIC Stamp is...

BASIC Stamps are small reprogrammable single board computers (SBC) that run BASIC programs and are made by Parallax, Inc. in US. At first glance, they may seem fairly minimal - and in fact, they are. But with software that fully utilizes all available hardware, the Stamps give you powerful features - without the cost of hardware.

Their low cost and simplicity make the Stamps perfect for many prototyping and control applications. It's suitable for electronics hobbyists as well as electronics professionals in many different areas.

Typical application areas for BASIC Stamp's are...

- General electronics
- Home automation
- Robotics
- Mini PLC
- Education
- Prototyping
- HAM related applications
- Special effects in films

- Industri control
- Geological instruments
- Computer peripherals
- Scale model hobbyists

As an talent engineer and technical writer expressed it...

- BASIC Stamp is the 555 of the 90's !

1.1 What is L.O.S.A all about ?

I started to compile L.O.S.A because I know there are lots of great ideas and many problems that are solved with the BASIC Stamp and the main purpose of this list is to get an idea of what other people are using their BASIC Stamps for and maybe get some inspiration or hints.

Remeber it's up to all of us if this list are going to be any good and I'm looking forward to receive a description of your application.

1.2 How can I contribute to this list ?

If you have done something with the BASIC Stamp (big or small) that you are willing to tell others please use the form given below and write a short description, nothing fancy is needed just a simple explanation. If you have source code to share that's even better but it's not necessary.

Then e-mail the form to:

cj@hth.com

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill in the L.O.S.A form on the Web-page...

http://www.hth.com/losa.html

Title : Robo-Cat [## 001]

==========

Date : 950807
Author: Gustavson Guy W.
E-mail: GWGUSTAVSO@mpg.norstan.com

Stamp model : BASIC Stamp Rev. D
Code available: N/A
Filename : N/A
URL : http://www.winternet.com/~bigfoot/cat.html

Description :

My cat, Kesha, was recently diagnosed with Heptic Lipodosis. Or "Fatty Liver", basicly what this means is that for some reason he stoped eating and his liver started converting body to useable sugars. The fat deposists biuld up in the liver and cause severe liver damage. Because the liver isn't working well the cat feels crappy and wants to eat even less. The treatment for this disease is to run a tube down down the cats nose into his stomach, or a PEG tube through the abomine wall into the stomach and feed the cat a liquid diet this way.

I love my cat, but I can't be there every three hours to feed him through the tube for a month. Something about work and deadlines and such. So I went to a local supplus house and got a tiny motor driven pump, a case, some switches, a micro switch, ect...

The micro switch is mounted such that the switch trips for every rotation of the pump shaft. The stamp turns on the pump for on a single rotation at intervels programable from the controll switches on top. An alarm buzzer and LED flash if the pump fails to run for any reason. The unit is programable for 9 differents deleviery rates.

Now he gets a slow continuious feeding and he seems to tolerate this better than the 100ml feeding every three hours.

==========

Title : Logic Rudder [## 002]

==========

Date : 950812

Author: Christer Johansson
E-mail: cj@hth.com

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : LRUDDER.ZIP
URL : http://www.hth.com/filelibrary/BS1-IC/

Description :

Many of the new and very realistic flight sims available today needs rudder to let you get full control. This one uses a digital pot from Xicor (X9104) and 10 other components. Connects to a standard IBM-PC game port and power is taken from the port.

It uses two micro switches for controlling the rudders left or right and to indicate when rudders move there is a red LED that lights up when you press the micro switches and to indicate center there is a green LED. If you press the both micro swithes the rudder will automaticly return to center position.

There is a trim pot to set the desired step rate from slow to very fast and the Xicor pot has 99 steps wich gives a fair resolution.

==========
Title : Interfacing MAX186 8 channel 12bit A/D [# 003]
==========
Date : 950925
Author: Helmut Fligge
E-mail: h.fligge@asco.nev.sub.de

Stamp model : BS1-IC
Code available: YES
Filename : N/A
URL : N/A

Description :

This Program interfaces the Stamp1 to the MAX186 A/D converter. Via RS232 2400bps the stamp is asked to measure channel numbern. After conversion the result will be returned to the host computer as an ascii string (0 .. 4096). Conversion rate is about 4 measures per second.

==========
Title : Scrolling LED Sign [# 004]
==========
Date : 950926
Author: Bob Blick
E-mail: Bob_Blick@redwoodfn.org

Stamp model : BASIC Stamp Rev. D

Code available: Maybe sometime
Filename : N/A
URL : http://www.execpc.com/~bblick/stamp.html

Description :

Scrolling LED sign, 35 super-bright LEDs in a 5-by-7 matrix in the prototyping area of a Basic Stamp rev D. A scrolling alphanumeric message moves one pixel at a time, just like real scrolling LED signs, except this one only displays one full letter or portion of two letters at a time as the message moves by.

==========
Title : Tone Decoder [# 005]
==========
Date : 950926
Author: Bob Blick
E-mail: Bob_Blick@redwoodfn.org

Stamp model : BASIC Stamp Rev. D
Code available: Soon
Filename : N/A
URL : http://www.execpc.com/~bblick/stamp.html

Description :

Listens for telephone touchtones, displays phone numbers on LCD screen and echos them out RS-232 port. Circuitry fits in prototyping area of rev D Basic Stamp:

Microphone preamplifier, touchtone decoder IC.

==========
Title : Pager [# 006]
==========
Date : 950928
Author: Don McKenzie
E-mail: donmck@tbsa.com.au

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : PAGER.BAS
URL : http://www.labyrinth.net.au/~donmck

Description :

This program for the Basic Stamp is used to monitor 4 hardware signals. If a change takes place, (after testing for a false trigger) then a cheap 2400 baud MODEM is used to dial into a Telecom Alpha-Numeric pager. It leaves a message which consists of a 2 digit I.D. (01 to 99) followed by the 4 signal levels of pins 3 to 0.

Status of the signal levels message: 0=Low, 1=High. EG: "011110"
means Unit "01" has pins 3, 2, and 1 high, and pin 0 is low.

A "Ring-In" feature is also included. By ringing the MODEM for a
short period, then hanging up, the Stamp will dial your Pager and
report the current hardware status of these four signals.

This program uses about half of the available memory, so if the user
wishes to add enchancements such as "Multiple Ring-In's" say within
a minute, for a command selection, there is plenty of program space
left.

==========
Title : HexWalker Mobile Robot [# 007]
==========
Date : 950929
Author: T. R. Thornton
E-mail: mandtsys@ix.netcom.com

Stamp model : BASIC Stamp Rev. D or BS1-IC
Code available: YES
Filename : WALK.BAS
URL : N/A

Description :

HexWalker is a six legged mobile robot that is controlled by a BASIC
Stamp or BS1-IC, and driven by three servo motors (similar to Futaba
S148). It is the simplest walking machine architecture that can walk
forward, backward, and turn left or right.

==========
Title : Robo Bug [# 008]
==========
Date : 951003
Author: David Novick
E-mail: dkn@cimar.me.ufl.edu

Stamp model : BS1-IC
Code available: YES
Filename : N/A
URL : http://www.me.ufl.edu/~dkn

Description :

Using two stamps, a robot with six legs (2 degrees of freedom each)
was able to walk and turn (at this stage, not very gracefully).

==========
Title : EXPBOT Robot controlled by Stamp [# 009]
==========
Date : 951009
Author: Marvin Green

E-mail: marvin@agora.rdrop.com

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : EXPBOT.BAS
URL : E-mail author and he will send it

Description :

This program allows a cool robot to move abound a room in search of light. Like a moth. Simple program changes can dramatically change the robots behavior.

==========
Title : Andrews Ever Evolving Lego Robot [# 010]
==========
Date : 951119
Author: Andrew H. Hochheimer
E-mail: softarts@ciaccess.com

Stamp model : BS2-IC
Code available: YES
Filename : N/A
URL : http://www.wincom.net/~softarts

Description :

Currently the robot can only navigate to the brightest light source in a room. It's current operation mode has four major steps: - Scan a 180 Degree Field of "Vision" taking light level readings, and determining the brightest direction of light. - Decide if it needs to turn left, right, or continue moving forward. - Check for collision with an object while moving, if a collision occurs, display the total travel distance on the display - Move forward for 1.5 Seconds and then repeat the process.

Currently I am using Two Futaba FP-S128 Servos (any RC Car Servos would work) one to sweep it's "sensors" form left to right, and one to "stear" the robot.

You can see pictures and more information on my homepage, just follow the lego robot link.

==========
Title : Factory Monitoring System [# 011]
==========
Date : 951120
Author: Paul Willemse
E-mail: pjwill@merlion.singnet.com.sg

Stamp model : BASIC Stamp Rev. D
Code available: YES

Filename : N/A
URL : E-mail author

Description :

The system presently consists of 4 Basic Stamp units. Each monitors up to 5 inputs. The inputs are 'digital' (switches) and/or analog (temp, airflow, current, etc using commercial sensors). All stamps communicate the results via serial mode to a Macintosh (Yes a Mac!) where the results are graphically displayed and monitored. Alarms are set for certain conditions.

The transmission is simple, one way only. Each stamp sends the info at a 'random' interval not exceeding 2 seconds. The message format is fixed, the Mac will throw away any conflicts in case two or more stamps transmit at the same time. BTW this happens very seldom. The max time any stamp can be 'absent' from the chain before an alarm is raised is six seconds (failure, transmission collisons, etc). This is controlled by the Mac.

The 'system' is presently in beta test, the client wishes to expand up to 20 stamps. At that point we will likely use the BS1-IC or BS2-IC on custom boards located around the facility.

Code is available upon request (e-mail) partial, some is proprietory to my client.

==========
Title : Wave to the Cats/Desk Temperature [# 012]
==========
Date : 951121
Author: Paul Haas
E-mail: paulh@hamjudo.com

Stamp model : BS1-IC
Code available: Yes
Filename : See web server
URL : http://hogwild.hamjudo.com/cgi-bin/stamp

Description :

The Stamp has a serial connection to web server, a cardboard hand, a servo motor to move the hand, and a DS1620 thermostat chip to measure the temperature. The web server can request the current temperature or start the hand waving. See the web page for the source code for the temp and the web server.

It's mostly useless. The cats ignore the hand. A few people find it entertaining.

==========
Title : Gamer's Die Roller [# 013]
==========

Date : 951122
Author: Larry Tremblay
E-mail: ltremblay@domus.com

Stamp model : BS2-IC
Code available: N/A
Filename : N/A
URL : N/A

Description :

The Gamer's Die roller is a little thing I am putting together as my first Stamp Project. The Roller allows cumulative rolls of n dice up to 256 sides, so long as the sum does not exceed 99,999,999(!)

It uses two 74HC161 4 bit counters cycling at 1MHz to draw random numbers off of. Input is achieved via a Grayhill model 38 keypad and a 74C922 keypad decoder. Display is on a Siemens PDSP-2111 8 character smart display (5x7 LED characters) fed by two 74HC164 serial to parallel shift registers cascaded so I can use Shiftout to feed 16 bits of control + data off of 2 pins.

The code is very simple, the most exotic part being the random numb-er generation. In a nutshell, it is:

Begin Loop
S = 8 bit number drawn from the counter (random)
if S < (255/N) x N (integer divide, N is number of sides on die)
exit Loop
End Loop

This gets (pseudo) random numbers whose average is not skewed downwards by the counter's max of 256 (i.e. a 100 sided die is not affected by the extra 56 in the count maximum)

Using gamer's dice notation, (5d6 = sum of 5 six sided dice, 3d10 = sum of 3 ten sided dice), the user can input whatever combination they wish, including just 'd6' for one six sider. The keypad I have has removeable keycaps with legends, so I have 0-9 plus 'd' and '=' on them.

As noted earlier, since I am using an 8 bit counter, the maximum die size is 256, although that could be fixed easily by sampling two, three or more times for each die.

Anyhow, that's it. When the code is done and debugged, I'll be happy to e-mail it to any who want it.

==========
Title : Stamp II Serial I/O [# 014]
==========
Date : 951128
Author: John Hansknecht

E-mail: Hansknec@cebaf.gov

Stamp model : BS2-IC
Code available: Yes
Filename : HAL01.bs2 and HAL01.bas
URL : ftp.parallaxinc.com

Description :

A bare-bones demonstation of 2 way serial communications between a
PC running Qbasic and 1 or more Stamp II's.

==========
Title : Voice and CW Fox Hunt Transmitter IDer [# 015]
==========
Date : 951221
Author: Sam Guccione
E-mail: sguccion@outland.dtcc.edu

Stamp model : Counterfeit Stamp
Code available: Yes
Filename : Revision of S. Edwards MORSE program
URL : N/A

Description :

An IDer based upon the MORSE program. Has 4 time delays as well as
a random time delay. Circuitry includes selection of a voice id
using the Radio Shack 10 voice board or the Walden bookstore 10 sec
talking gift card. This is a very simple circuit and program but was
developed by my students under my direction.

May be of interest to someone out there.

==========
Title : Lift (elevator) Controller [# 016]
==========
Date : 951225
Author: Dave Bell
E-mail: dbell@cup.portal.com

Stamp model : Faux Stamp (BASIC Stamp clone)
Code available: Yes
Filename : Upon request
URL : N/A

Description :

A simple control loop monitoring lift Call buttons (with debounce)
and Limit switches, forbidding manual control past limits, and en-
forcing a Stop before reversal of direction. This will be used in
an owner -designed and -built single story platform lift for a home.

```
=============================================================================
Title : Paging with the Stamp [# 017]
=============================================================================
Date : 960104
Author: Kurt Clement
E-mail: kclement@kraft.com
-----------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: Yes
Filename : monitor.bas
URL : N/A
-----------------------------------------------------------------------------
Description :

Use the Stamp to monitor several inputs, two temperature and two
contact closures in this application. When inputs go outside set
limits, dial pager and send coded message. Used to monitor power
failures and temperatures for computer and network equipment since
August 1994, running on 9 V power supply from one of the UPS units.

=============================================================================
Title : Switching Sytem [# 018]
=============================================================================
Date : 960109
Author: Alexander Avendano
E-mail: aavendan@aros.net
-----------------------------------------------------------------------------
Stamp model : BS1-IC Module
Code available: N/A
Filename : N/A
URL : N/A
-----------------------------------------------------------------------------
Description :

I'm almost finishing a Basic Stamp Based Switching System (Small
Phone system) which I consider very usefull for small companies that
cant'n afford other brands. This is designed with a host computer
which will have a vox-mail and all the functions like big ones to
choose. I'm using BS1-IC's for the extensions process right now.

As soon I have complete it I will give the code away for small
Intelligent Switching phone system up to 2 Lines and 4 Extensions
using the L.C.D serial circuitry for information display. I forgot
to mention that the computer (Host for many processing functions)
will be running under Windows 3.1 and Windows 95, making this way a
usefull computer not only for the phone system but for ithers
application at the office.

Please be free to send me E-mail, about any suggestion.

=============================================================================
Title : Door Entry Card Reader [# 019]
=============================================================================
```

Date : 960110
Author: Ed Buckley/J J Barbarello
E-mail: ed@milinst.demon.co.uk

Stamp model : BS1-IC Module
Code available: YES
Filename : N/A
URL : N/A

Description :

Stamp 1 based version of the Card Reader article by J J Barbello as described in the August 1995 edition of Electronics Now. This version uses the Stamp 1 as a local controller determining the card number and deciding whether or not to allow door opening. Optional serial comms back to a master controller and optional local message readout using an LCD Backpack.

Lots of scope for further enhancement/experimentation. Circuit schematic and listing available.

==========
Title : Telephone Card Reader [# 020]
==========
Date : 960119
Author: Francesco Volpe
E-mail: f.volpe@ee.mu.oz.au

Stamp model : BS2-IC Module
Code available: YES
Filename : TELEMARK.LZH
URL : ftp://ftp.ix.de/pub/elrad/010/

Description :

The BS-II is used to read a German telephone card, which is a smart card. For more details see the German Electronic Magazine ELRAD (http://www.ix.de/el).

The data is transfered via RS232 to any terminal program.

==========
Title : DTMF Decoder [# 021]
==========
Date : 960125
Author: Joe Altieri
E-mail: radioman@banished.com

Stamp model : BS2-IC Module
Code available: YES
Filename : DECODE.BS2
URL : N/A

Description :

A new parallax BASIC Stamp II program for decoding a nine digit DTMF sequence of "Touch Tones" for remote activation/de-activation of any electrical appliance via Ham Radio, radio link, telephones, intercoms, etc.

==========
Title : Ion chamber radiation monitor [# 022]
==========
Date : 960125
Author: Jeffrey L. Rothman
E-mail: rothman@bnlls1.nsls.bnl.gov

Stamp model : BS1-IC Module
Code available: YES
Filename : RADMON12.BAS
URL : N/A

Description :

A Basic Stamp monitors the operation of an ion chamber radiation detector. The ion chamber and related circuitry produce a signal with a frequency proportional to the dose rate. The Stamp measures the frequency and calculates the dose rate and total integrated dose.

The results are displayed on a log scale panel meter and an LCD respectively. The dose rate is also transmitted over RS-232 to a remote PC.

A Front panel button allows the user to reset the total integrated dose. Another button allows the audio alarm to be muted at low dose rates.

==========
Title : Barn Monitor [# 023]
==========
Date : 960203
Author: Lynn A. Roth
E-mail: lynnr@hesston.edu

Stamp model : BS2-IC Module
Code available: YES
Filename : N/A
URL : E-mail author

Description :

The Barn Monitor checks the temperature in 5 rooms of a farrowing house. The temperatures are taken by DS1620 chips.

If the temperature goes outside the limit set by the farmer, the Stamp dials a pager using a 2400 baud MODEM. The same occurs if the power goes out.

```
=============================================================================
Title : Dallas one-wire interface [# 024]
=============================================================================
Date : 960212
Author: Daniel G. Clemmensen
E-mail: dgc@shirenet.com
-----------------------------------------------------------------------------
Stamp model : BS2-IC Module
Code available: YES
Filename : N/A
URL : http://www.shirenet.com/~dgc
-----------------------------------------------------------------------------
Description :

As part of a furnace controller project, I've interfaced A Stamp II
to a string of Dallas 1820 digital thermometers. The interface
consists of three cheap IC's and some subroutines. A design note and
a demo program are available on the web. I have successfully tested
the interface with a string of twelve 1820's.

I have not yet tested it with other one-wire devices, although I
will update my web site when I do.

=============================================================================

1.5 Credits and other things
----------------------------

Credits should go to all of you who makes this list possible I hope
it suffices to say "Thank you to all who have contributed to L.O.S.A
- we all appreciate it."

Special thanks to all of you at Parallax, Inc. who makes and support
this great products !

If there is anything you think I've missed (or spelled wrong <g>) I
would love to hear from you so we could make this list even better.

You could reach me at the following e-mail address: cj@hth.com

Stay tuned,

/Christer

1299. Re: ### KISS on a Baycom?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-20 00:00:00 UTC
From: Helmut Strickner <hstr@ipswich.gil.com.au>
Message-ID: <Dn20p2.LpF@gil.com.au>
Source record: 107127

Hi

There are a number of KISS drivers around for the Baycom - style modem.

TFPCX
TFX
probably some more that I dont recall off the top of my head.

For NOS use AX25.COM from Pawel Jalocha.

Helmut VK4STR

>funny- I've built a number of walkie talkies, not loaded or anything, but
>they had good range. I was just hoping to find info.

Yeah, with today's high integration chips, building a HT isn't very
hard. Building a GPS receiver is a bit harder, but again thanks to
high integration chip sets it isn't very hard either. I handled such
a unit at Dayton a couple of years ago at McNasty's. Tom Clark built
it for AMSAT. It's scheduled to fly on P3D. There aren't many parts
involved, but they are very high integration. Motorola, and others,
make the GPS chipsets. You need to add a uP and some software to
make it play.

As you probably know, GPS uses spread spectrum, and the real trick
is to get a sync lock on that and despread it. The chip sets do that
for you. After that you just have to do some housekeeping and number
crunching to get the navigation data into a useful form.

I agree with the other poster, however, in that it is easier and
probably cheaper just to buy a commercial handheld GPS receiver
rather than trying to roll your own. The only reason you might
need to build your own is if you have special circumstances, like
operating *above* the GPS constellation as P3D will. You likely
can't buy the chip set in quantity one as cheaply as you can buy
a Garmin 45. (If you were buying thousands of chip sets, you could
get a huge price break, but at quantity one prices I don't think
you'd save any money.)

Even if you need special features, it might be cheaper to start
with a complete GPS receiver and just modify it to do what you
want. I understand Motorola will sell you the core chip set for
$150 if bought in quantity 100, but you can buy a low end Trimble
or Garmin brand new for $200, or a used Icom or Sony for considerably
less. That way you *start* with a functional unit.

>gives them more than a line or two of "Tunnel diodes can also be used to
>generate microwaves."

Tunnel diodes have pretty much been abandoned since microwave GASFET transistors have become available at reasonable prices. Look in older ARRL Handbooks (mid-70s) for some circuits using tunnel diodes. Typical oscillator circuits would have the tunnel diode mounted in a post cavity resonator so that there's a 360 degree phase shift from the diode to the cavity far end and back, IE halfwave cavity. You just need to adjust diode bias current into the negative resistance region and you'll have an oscillator.

As with most such simple circuits, stability isn't very good, and harmonic and subharmonic oscillations are possible too, IE it sort of is the spark gap of solid state microwave oscillators. You can injection lock one to a stable source, but that's more trouble than it is worth.

Look for the lowest cost part with decent availability, not someone's
favorite processor. The Atmel 89C2051 is a 20 pin 8051 processor with
1 or 2 K of on-chip EEPROM. The PIC processors come in a dozen
different flavors.

We really can't tell without doing more of a feature/cost brainstorm
session, but HC11 or 68HC05 or 80C51 might be overkill in power and
cost. I believe it is Wayne Burdick that already supplies a memory
keyer in a PIC for a QRP kit.... maybe he'd make a variant of the
source code PD?

Dana Myers (myers@West.Sun.COM) wrote:

: I'm not familiar with LTC Design Note 7, but I'd guess they're
: using the 4046 in some application other than a radio transmitter
: or receiver local oscillator.

I've just had a look at LTC DN7 page 2. I think you're dead right,
Dana.

Fig D is nice, a scope shot of a rising edge showing about 1us of
jitter at an output freq of 6kHz and a ref freq of 60 Hz.
With an RC filter they show about 30us of jitter.

OK, that's quite an improvement, but the 4046 VCO is spectacularly
nasty open loop. Current/voltage/ Capacitor VCOs like RC oscillators
have Q's less than 1

From the text, the thing seems to be a clock multiplier intended to
drive a tracking switched cap filter - presumably to filter a mains freq
signal.

Cheers,
David GM4ZNX

1308. .5Mc up to 12Mc antenna

Hello all. I've got a short wave radio that has a range of 3 to 12Mc.
And it has the AM channels also from .5 to 1.7Mc. But it has very very poor
reception. Almost no channels come in. I guess that it is my antenna that
came with it is very poor for these long wave lengths. I have lots of
acreage and want to make a long wire antenna to hook to it. I need some
help here on the best design to pick up all frequencies in this range.
Could someone help me here. Could I get a good ferrite core antenna?
or use different rhombic lengths/ or straight wire. HELP! It's got to be
cheap. If two or three different antennas are needed let me know and I can
make them selectable when I switch to AM or Short Wave or go up the range
in short wave. Please give me full details.

Hoping to hear from someone,
There is lots of stations on AM and Short Wave with good info if I could
just get them
Lyle Murphy

Oh no!!!! At least you can still buy discrete JFETs and bipolar transistors, build an oscillator, and either build or buy a diode ring mixer. If you really want gain in front of the mixer, you can use another discrete transistor to build a preamp....

;-)

1310. new rigs now tested with Wilderness Radio's KC1 keyer/counter

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-20 00:00:00 UTC
From: wayne@interval.com
Message-ID: <wayne-2002961157570001@burdick.interval.com>
Source record: 107138

In addition to the list of rigs in the current manual, the KC1 keyer/freq. counter has now been successfully installed in the following rigs:

"A Small High-Performance CW Transceiver for 20m," Nov'95 QST, by Rick Campbell, KK7B (installed by Dave, KE6ZBZ)

MFJ 9420 w/CW adapter (Mike, AC6JA)

OHR Explorer I (Tom, WA1GUV)

OHR Explorer II

NorCal Cascade (Rob, WA3ULH)

* * *

The original list of rigs includes:

NorCal 40 (all versions), Sierra (NorCal), Heathkit HW8 and HW9, SWL XX-40 (Small Wonders Labs), OHR-400 (Oak Hills Research), and the Gary Breed transceiver (A&A kits and 624 kits).

* * *

If you know of others not on this list, please send them to me. I will be incorporating instructions for all of the new rigs in the next release of the KC1 manual.

The KC1 is a subminature (2.5 x 0.8") universal Iambic keyer and displayless frequency counter (3-digit Morse code output) for QRP rigs. For more info contact Bob Dyer, KC6VIO at 415-494-3806.

>unconnected parts. I could try the doors and rear gate .

Properly setup VW's are generally pretty good in this respect.
I suggest you check three things: distributor rotor, spark plug
connectors, and your antenna cable.

Use only OEM Bosch rotors and spark plug connectors. The rotor should
have about 5K Ohms built into it and the spark plug connectors should
have about 1.4 K Ohms. Cheap replacements lack the resistive elements
that damp the oscillations in the spark.

Check your antenna cable to verify that its shield is continuous to
the body of the car. You must unplug the cable from the radio to
check this. It is common for the cable to become disconnected
(corrosion, I assume) from the body at the base of the antenna.

Hope this helps.

FRIENDS,

If you would like a free copy of a radio database program that covers longwave, mediumwave, and shortwave with at least 4,000 of records, send your NAME, POSTAL ADDRESS, and EMAIL address to chuck@flinet, and I will return the program to you via EMAIL.

The program is not up to date! It is a program used during 1994 and hasn't be updated since. However, many of the records are still current for stations that do not change every quarter.

The program is good until June 6, 1996. After that it will not function.

Hope to hear from you and don't forget your Postal Address for registration and future information via mail..

All addresses will be kept confidential!

Chuck

I have a keyer built on a New Micro's 68HC11 board. The memories are
programed via rs232 and has 6 memories implemented several more could be
implemented. It is written in the FORTH that comes resident on New Micro's
chips.
I also have a start on a keyer in C for about any thing that will run C. It
only sends from memory.

Both systems use a port hooked to a pizo speaker for side tone. I originaly
did this for output from the 68hc11 so I could debug code.

I would be willing to release them for non commercial use to anybody that
wants them on an as is basis. I will not support users for money , I sure
won't do it for free.

Source record: 107155

The HW-100 and 101 were originally designed and will work just as well with 6AU6's. Because of the series/parallel arrangement that Heath used on the filaments and because the 6HS6 heater is 450ma @ 6.3V vs. the 300ma of the 6AU6, you need to change both of the 6HS6 units at the same time. They are the rf and first receiver mixer tubes as I recall. If you look closely at the schematic you will probably note that the schematic still shows the 6AU6.

By the way you may want to check the 33K ohm plate resistors on the 12AU7 carrier oscillator. They generally are found to have drifted very high in resistance - up to 100k to 400k ohms. The output to the ring modulator eventually suffers, affecting available drive on one or the other sidebands!

Wow! Tunnel Diodes are Cool!
Seriously Bruce, they are kinda slick. They act like a series resonator. Most of them were very low power, milliwatt range. They were invented in 1959 by Dr. Leo Esaki who was an IBM Fellow at the time. They were weird in that they operated in 'negative resistance regions.' The biggest thing you have to watch out is the power applied to them. I seem to think that they didn't like anything above 1.2 volts. One of the more popular ones was I think a 1N2939. Don't hold me to it, this 'old' brain has turned a lotta cycles since then. If you can find and old General Electric Transistor Manual, they had experimenters circuits with TD's Texas Instruments also built them. I'd love to get my hands on one of them for my 'old semiconductor' collection. I've got a 'in the box' CK722 and 2N107. Whew, those are old! The 2N107 had a 'evacuation tube' on top to make you think it was a little vacuum tube.
I did a 'Science Fair' project centered around the Tunnel Diode in 1961 and won first place at the Chicago Museum of Science and Industry with that project, so you made me laugh when I saw your post! I'll look around for some old circuits, by the way they also act like an astable multivibrator (flip flop) and are resonant across a freq range that will have you scratching your head.

I had a neighbor that drove me crazy, and I built a little 'shoop shoop' xmitter that ran on a single solar cell and a nicad battery, and put it up in his gutter one night, that guy bought 3 TV-Stereos trying to find one that wouldn't go 'shoop - shoop' whenever he turned on his set. Of course the low power only effected him..... The crazy thing pranks high school nerds do!!!!!!!!!!!!!

HAMMARLUND MINIATURE AIR VARIABLE CAPACITORS

::::::::::::::::::::

TYPE APC

Compact, hi-quality variables. Isolantite base. Screwdriver
or hex-wrench adjust.

APC-25 3.0 - 25 mmf 10 available
APC-140 6.7 - 140 mmf 3 "

TYPE MAPC

Midget padding, trimming and general purpose capacitors similar
type APC but smaller. Ideal for small space applications. Gap
.0135 inch. Rotors and stators are nickle-plated brass.
Nickle-plated beryllium copper wiper contact. Tapped (4-40
thread) brass studs in Steatite base permit mounting without
grounding rotor. Tested at 600 volts rms, 60 cps. Slotted
shafts for screwdriver or hex wrench.

MAPC-75 3.9 - 75 mmf 7 available
MAPC-25 2.6 - 25 mmf 18 "

TYPE ???

Identical in size and shape to the type APC, but have military
part number. Rotors and stators are silver plated (tarnished).
Please note that capacitance ranges and values for this
particular group are APPROXIMATE, subject to the accuracy
of my RLC tester.

922-0004-00 2.5 - 30 mmf 10 available
CA-290 3.5 - 60 mmf 8 "

::::::::::::::::::::::

Would anyone out there care to make an offer on these little jewels?

Yuck.
It seems that every IC I know has a lot of phase noise and 3362 is no
exception.
The best VCO remains a discrete LC type.
Depends on what you're planning, though. On HF, it is surely not worthy
boring oneself with that kind of considerations.
At 1296 MHz, it is another story... :-)

In our county, I have seen some stickers "NEED HELP - CALL YOUR SHERIFF". This might seem a bit farfetched for your problem, but think of it. Those guys drive in cars, and they are radio equipped. Just call your local office and ask your way through to the guy in charge for maintaining the cars. That guy should know all the tricks about grounding. And chances are, it might be a ham, too :)

At least, it wont hurt to try it that way.

I've had a look inside the 8K, but actually didn't check out the schematic. It
uses motor tuned roller inductors and homemade relays to switch in fixed
capacitors. These (relays) have been a real pain in the butt for him as the
open contacts tend to arc over. This then explodes the capacitors that get
connected into the circuit via the arc. A lot of polishing and radiusing have
been done to minimize corona, but I believe the fundamental problem is just
not enough spacing on the open contacts.

Damn Tom! I never thought of my Alpha 77DX amplifier as a weak-performing sissie! And what of those 3CX800-based pansie amplifiers?

Actually, I've been giving serious thought to the new Henry 3K Ultra. A colleague of mine recently purchased the 8K Ultra and uses a Yaesu FL-7000 amplifier after his TS-940 as an I.P.A stage. The 8K's 3CX3000A7 requires *at least* 200 watts of excitation to really give the plate a workout <g>.

Have you had a chance to review the circuit of either amplifier? I am particularly interested in its efficency on 160M. On the surface, it looks like the last of the commercially produced real-man's amateur amplifiers.

Source record: 107167
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Is/was there available a HF receive option to the Yaesu FRG9600?
There's a blank spot on the board for the module. The software and PLL are set up to receive from zero to 999 MHz. if you use 73 MHz. first IF and high side LO injection.

Has anyone ever tried to build such an option?

Anybody interested in working on such an option? Except for the availability of the Xtal to get from 73 MHz. to 45 MHz. it should be pretty trivial.

1340. Ideas on a power antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-21 00:00:00 UTC
From: hillgen@remus.rutgers.edu
Message-ID: <4gg0i6$qat@remus.rutgers.edu>
Source record: 107168

Here's my idea. I have a Lincoln Continental that I'm absolutely in love with and I really would like to have my 2m radio in it but I'm not too eager to slap a mag-mount on it or even (gasp) drill holes in it so i have an idea for a compromise. How feasable would it be to build some sort of matchbox so that I could run realtively low power (50 watts or less) at good SWR through the power antenna used for the FM stereo. I figure that if it works, I'd mount a second in the fender and it could retract out of the way when not in use. I figure that it would have a good ground plane but how would I achieve a good match? All advice appreciated! If this idea doesn't work out, anybody have any others for a rather inconspicuous antenna?

Thanks!

From: Jim Potter <jpotter@jpaw.com>
Message-ID: <312BE838.1188@jpaw.com>
Source record: 107170

Somewhere in my collection I have an FM receiver that used a tunnel diode as a local oscillator and mixer. I believe the circuit came from the RCA tunnel diode handbook, but I forget. The IF was roughly 300 kHz and used about 4 stages of 2N1308 current switching pairs as limiters. The detector was a pulse averaging circuit. A one shot fired with a fixed width pulse at every zero crossing and the audio was obtained by passing the pulse through a low pass filter. It actually worked pretty well considering tthat it only had one inductor in the whole thing. I do remember that it was susceptible to interference from AM stations idf the antenna lead got too long. I just used the classic twin-lead folded dipole tacked to the wall. It was the source of background music in an electronics lab I worked in circa 1963.

Hi Edwin,

You did not mention in your first posting that you want to use the Baycom
modem on a *NIX system.
Of course the ax25.com driver can only be used under DOS.
It takes quite a bit of CPU power to use the driver due to its function
of bit timing etc.

There is possibly a driver for Baycom modem out there which runs under
LINUX but I dont know. Your best bet is to put a posting in the .linux
newsgroups.

What is your reason to run TCP/IP on a UNIX platform, there is a lot of
programmes available which run on DOS and can do all you need.

If you need a unix platform and want to use the Baycom modem why dont you use a low cost PC 286/386 as front end and network it to your unix machine using TCP/IP?

To get more response I would also suggest to use the more appropriate newsgroup rec.radio.amateur.digital.misc, there are far more people with the knowledge required to help you reading your postings. Most computer guys are not really "into" homebrew.

1344. MOSFET X-Ref: help!

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-22 00:00:00 UTC
From: zimmie@gti.net
Message-ID: <4ggmnn$6ia@gti.gti.net>
Source record: 107172

Recently an audio amplifier of mine ceased to work. Upon smelling
fried semiconductor, I opened the case and found two of the power supply
FET's fried. I assume they are MOSFET's since the company boasts of it
being a mosfet amp.

All four (there are two banks of two) FET's are the same;
however, I cannot find any cross-referance to the number on them. There
is an emblem on the case (TO-220) that appears to be "ST" in reverse
text, followed by the number 9448. There is also a number, P30N06,
towards the bottom of the case. I may be wrong, but from following the
circuit, these devices seem to be N-channel. Although it would be
bennificial to try to track down the cause of the failure, I would like
to try replacing these devices first, if the cost is not high. I would
greatly appreciate it if anyone can help me find these devices or give me a
cross-ref part number.

Only one caution; the first time that I downloaded a large datasheet
using pdf, my system warned me that it was possible to imbed macros
and viruses in the pdf documents that could disrupt your system - and
therefore to only download documents from sources that you trust.

I don't know much about Acrobat and the pdf format so I can't verify
the accuracy of the warning, but I have no reason to doubt it. Other
than that caution, I agree it does result in very nice looking
documents and in more compact form than postscript.

A company here in Scottsdale stocks a great many RF-related ICs and some transistors, and their customer service is superb. They're called DC Electronics, on Scottsdale Road. (I don't have an address or phone for them here at the office, but they're in directory assistance.) By all means get their catalog. I've bought most of my NE602s from them, as well as the Motorola RF chips like the MC3362 and MC2833.

From: Jim Devenport <jdevenport@lanl.gov>
Message-ID: <312C9863.5133@lanl.gov>
Source record: 107181

BAYCOM refers to software that allows a PC to be used as a Terminal Node Controller (TNC) for packet radio communications. All functions except tone-to-digital (modem) functions take place inside the computer itself, thus requiring a relatively simple and inexpensive modem to interface the radio to the PC. This software was originally developed by the German authors for the Commodore 64/128 machines which was called Digicom.

From: elendir@enst.fr
Message-ID: <4gho2f$51t@tempo.univ-lyon1.fr>
Source record: 107182

Hi,
do you think that a diplexer such as :

- Having less than 1 dB of insertion loss at 1297 MHz.
- Having more than 80 dB of attenuation at 1291 MHz

can be built using "standard" (not microstrip, but with rods) comb or
interdigital filters ?

A cavity filter costs more than $750, it's too expensive for me.

I'm surprised that nobody has suggested AM broadcast surplus as a good source for 160 meter amplifiers.

Check out a copy of Radio News. You'll pay a bunch for a working unit, but you may also get a line on a "fixer-upper" that's not quite good enough any more to run 8760 hours a year.

If you can wind 1/4" copper tube around an oatmeal box, you can convert an FM broadcast transmitter to 160....

hillgen@remus.rutgers.edu (Fender) wrote:
> anybody have any others for a rather inconspicuous antenna?

I don't know if these are still available -- a few years ago, there was a stick-on 2 meter antenna available that looked like some kind of car alarm decal. You'd just paste it inside a window. Performance reports were good, considering the style of antenna (couldn't touch a 5/8 whip on the roof, but it would take > 50 watts).

You might also consider some of the on-glass antennas, if you don't mind having people think you have a call phone.

Both of these would be simpler than loading up the FM antenna.

1358. PIN Diode I-V ??

Source record: 107186

Hi guys,
I'm building an X-band BPSK transmitter and need to know the I-V characteristics of typical PIN diodes used in a double balanced mixer? Altough not elegant, I intend to directly modulate the carrier by applying the NRZ to the LO port of the double balanced mixer which cost about $700 each. Hence, I need to control the drive to stay within budget.

Thanks in advance, Clyde.

1365. Re: Are Ten-Tec Transverters Any Good?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-22 00:00:00 UTC
From: Francis Lyn <lynf@candu.aecl.ca>
Message-ID: <4ghotj$72m@shpk1.candu.aecl.ca>
Source record: 107193

A friend and myself both built up the TenTec 6 m transverter last year. It's a well designed piece of gear that performs exceptionally well. It is complete, well documented, and not hard to put together. I use mine with a Kenwood TS50 to get on to the new 6 m repeater just put in service by the local club.

This transverter is exceptional in that it has everything necessary built in; input attenuator, T/R switch, and 3 connectors for the antennas/rig. No messing about with T/R switching signals from the rig.

The only small gripe I have is that the PCB board could have been of a higher quality, but hey, what do you expect for a kit costing $100! Technically, the PCB board supplied does the job just as well as a an epoxy-glass board would.

I think that QST had something on this over 20 years ago. People used to remove the glass envelope from the valve base, and the electrodes, and wire a couple of JFETs, Rs and Cs across the pins in a cascode configuration. In many cases the replacement 'valve' worked just as well as the glass variety, and didn't need any other component changes. At least one company actually manufactured such devices.

: to be reproduced?

There were various fet based valve replacements, but they never equalled the originals. Those valves ran appreciable amounts of anode power and so gave quite remarkable dynamic range. Designing a semiconductor circuit to fully equal a bottle in the same impedence environment would be a major undertaking. Power VMOS fets can do the power, but have electrode capacitances much too large to be absorbed by adjusting the coupling circuits.

You could make the think work with Jfet-bipolar cascodes, but you'll lose the wonderful linearity of the HRO.

Sorry,
David GM4ZNX

1368. 49 mhz to 6 meter conversion

Antenna Specialists offers a line of "disguise" antennas to the police
market for undercover use. They replace the stock factory entertainment
radio antenna and *look just like it*. Under the fender they're different
of course. Models are available for VHF and UHF, *and* the entertainment
radio still works too thanks to a duplexer circuit included with the
antennas.

These antennas aren't listed in amateur catalogs, just in police
supply catalogs. Check with your local PD radio shop, or talk
directly to Antenna Specialists to see if they have one for your
model Lincoln (probably so since it shares antennas with other
Fords). You could build something similar, but the mechanics could
be somewhat daunting if appearance is important.

From: af104@detroit.freenet.org
Message-ID: <4gj9k5$nrs@detroit.freenet.org>
Source record: 107198

I'm having the dumb problem of not being able to swing the
needle all the way over to the 1.5V marker by adjusting the DC
calibrate pot. All wiring is correct, and the 12AU7 is just
fine.

Double checked the wiring - it's correct, with no apperent
cold solder joints. Correct components in place.

I wired this myself recently, and just cant "calibrate" the
meter.

Anyone know of any mods / errata on this VTVM? it
's the wide one with the large meter. The box pivots in a
"U" shaped mounting bracket.

Probe is fine. 1.5V voltage source fine. This is stupid, but
just can't get it to calibrate!

Thanks,

Jeff

>next project.
>
>David Lawson
>KF4EBP
>
I have done it. It is really quite simple to change over the 1 channel
units that are crystal controlled. If you order crystals order wire leads
so that you can lay over the transmitter cystal over on the board (if you
use the hc18 style and mount it vertical you will not get the case closed)
Tuneup is straighforward. You might want to add a small pot to the fixed
resistor squelch circuit to loosen up the squelch and come up with another
type of antenna (at 50mw you still have only a 1/4 mile range tops with
the antennas on these units. A decent antenna or beam can really help out
on range).>

Source record: 107206

Hi Jeff, I can't think of anything obvious but there are a couple of things that you can look at.

1. put the meter in the ohms position with the probes disconnected or open. Does it read full scale now? This also puts 1.5v onto the meter circuit but without the DC input attenuator in the circuit. If this doesn't give you full scale (you might have to adj the ohms adj), then the problem is most likely in the 12AU7 & meter circuit. If it does look normal, then the problem is most likely in the probe and attenuator circuit.

2. You didn't say which model, but if it has the combined AC/DC/OHMs probe, try putting the probe switch (not the mode selector) into the AC/ohms position while probing the 1.5v battery. This will bypass the 1m resistor in the probe. If the meter now adjusts to full scale it suggests that the input attentuator has too low a resistance and the 1meg in the probe is dropping the voltage. If you have a good DVM you can try measuring the input attenuator resistance (do this with the VTVM power off and the plug pulled. Then just connect the dvm probes to the VTVM probes - you should get 11meg).

Let me know what you find----we'll get it working....Jay

Vincent,

I'm a filter engineer by trade, and this sounds like a tough job.
I presume there is a passband required and a stop band required, rather
than just two spot frequencies. If this is the case, then I don't
think an all pole Chebyshev would be up to the job; you'd probably need
a ridiculous number of poles and resonators about half a metre across.

For comparison, we cellular guys have a passband requirement of
<1dB from 880-915MHz, > about 60dB attenuation 925-960MHz, and usually
use 7 or 8 poles and a couple of finite frequency zeros a la elliptic
filter to do the job. Tough to design and tune if you don't have either
a) a deep understanding of filter theory or b) lots of brute force
computing power and a very good optimiser.

In short, not the kind of spec *I* would look forward to, and I get paid
for this.

I know this doesn't help, but I just thought I'd throw in the
professional perspective.

Cheers,
Gareth.

: can be built using "standard" (not microstrip, but with rods) comb or
: interdigital filters ?

: A cavity filter costs more than $750, it's too expensive for me.

I have designed and built interdigital filters using ~10 mm diameter
brass rods in copper boxes with various numbers of sections. These work
very well, give stable and repeatable performance due to the basic high
Q of the resonator. However, I agree with the other response that
simultaneously achieving low insertion loss and high stopband that close
is going to be a challenge for this kind of implementation.

I suspect that to get that kind of performance you'll find yourself
with larger volume structures or at least a lot more elements.
It may start to look a lot like the $750 implementation you mention.

If I were trying to do it, I think I'd investigate inexpensive ways to
make the highest Q resonator I could, almost certainly a copper or
silver cavity of some kind. Once determined, I'd see how many of them
it would take to get the required performance.
Having some machining capability will no doubt help here.

If you are interested in a lesser filter, I'd be happy to supply the
design of a ~.5 dB IL, ~30 MHz wide interdigital filter I've built.
They're easy to fabricate, cheap and perform well, though not even close
to what you are asking for.

The only place you might trip up is not having enough "travel" on any
of the little can coils to bring resonance up by the 2-3 Mhz it might
take. Some of the cheapies use "naked" wire coils that you can spread
out to reduce inductance, but it's not an exact science and make take
some futzing.

You might give it a shot and let us know how you do.

Wait... there may be a better design coming up soon in the DUBUS
magazine. The G4HGT design works well but is not easy to get going -
mostly because of the difficulty in preventing Norton amplifiers from
oscillating.

Hi Jeff,
If you have another meter, you just might want to check the B+ and the other voltages to the tube. Even though you have a good tube, you may not be putting the correct DC levels to it. Good luck.

Have you ever considered an 'on glass' antenna? It'll do just about every thing
you want except retract. In that case you, unscrew the antenna mast and toss
it in the back seat. It'll be a lot less hassle in the long run. They run about $50
for a pretty good one.

1386. DigiBrain Spur/Noise Elimination?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-24 00:00:00 UTC
From: rohrwerk@netcom.com
Message-ID: <rohrwerk-2302962250450001@10.0.2.15>
Source record: 107214

March QST's refinement of the DigiVFO (adding a microprocessor and "knob" tuning with display) looks wonderful. It raises, of course, the same question I had about the original: additional circuitry needed to "clean up" the output to avoid spurs on receive. (Spurs at only 70 dB down can mean lots of receive birdies!) I'd love to apply it to my R2 setup, but not at the price of tons of spurs and noise!

A good PLL is of course the obvious solution... but I wonder... I am using a 74HC240 buffer to generate square wave drive for my system... similar to the buffer of the "remote VFO" project a while back. Would this tend to take care of those spurs and noise, the chips responding only to the main (strongest) signal in shaping the square wave?

Source record: 107223

I've got an old laptop (386) Im going to dedicate to the ham shack, mostly to run Hamcomm, Baycomm, and perhaps JVFAX. It has a 15 pin output for a VGA monitor, since everything I'm running is CGA and even then, mostly text based I want to use an amber monitor pulled out of a terminal. As best I can tell there are 3 inputs to the monitor for horz,vert, and video. (I may not have those terms correct but I know they are the minimum nessesary) I've successfully connected it to an old Sinclair Z-80, but dont want to blow the video out of the laptop.

Any suggestions on which pins will provide the nessesary signals. I'm just not up on the types of signals comming from the 15 pin video out.

Thanks for any and all input.

Something that might be easier to find is the Proceedings of the 9th
Computer Networking Conference of Sept. 22, 1990 in London, Ontario.
You might be able to get a copy from the ARRL. There is a about 45
page article by Dan Doberstein on building a GPS reciever (at least
the RF parts) But like others have said, its hard to justify the
years of work that would be required when you can buy one for a couple
of hundred bucks. (building one would undoubedly be more expensive
just counting the parts) 73s jim kb3kj

John,

I have nothing but good things to say about PnP Blue.

I had some initial missgivings about it, because I had previously tried to use normal overhead transpanancy film to build a printed circuit board. This was a total failure.

The difference is: the PnP Blue "film" has a coating of (big surprise) blue "stuff". This blue stuff adhears to the toner (from the laser printer, or photo copier) and adds resilience to the resist once it is stuck to the
Cu.

A couple of tricks:

1) Make sure that the board is absolutly CLEAN.

2) Make sure that the board is absolutly CLEAN!

Even one finger print will cause the resist to transfer improperly. I finaly used a laquer thinner to get the board to that final level of clean (while wearing latex gloves).

Another problem that I've had is that registration of a double sided board can be a bit tuff. Don't give up, it can be done.

Several things I DON'T know:

I have not as of this writing:

Tried to produce a board which had traces smaller than 24 mills.

Tried to run a trace between the pins of a 100 mill center component.

On the whole, I am very happy with PnP Blue. I recomend it for small runs of PC boards with the above provisions.

Good luck

The TS-820S that I had only required the DS-1A (2 Transistors & Heatsink). The
original transformer had separate winding for the DS-1A. Worked very nicely.
I wanted to build my own, but could not find the transistors at the time
(early 1980's)

Hi there,

Nope, as far as I know, theres no way possible to "do" a baycom on
Linux, beacause it's a multithreaded OS. Baycom relies on interrupts to
it's native DOS environment, and the Linux system has no way to this.

I think i'm on the right path here, corect me if I'm wrong :)

Hi,

Freq is 77 Khz (easy enough, it's called DCF77).
Take a look at some Elektuur (or whatever it's called in your national
language if there is an edition), you should be able to find
more info.
I have 2 clocks (one analog other digital) running on DCF77,
nice gadget makrr are CITIZEN and JUNGHANS.
There a lot of clocks available quite cheap from german company.
Also interface for PC (and Mac ?).
Hope it help,
Thierry

Danny:

For audio DSP - the Texas Instruments TMS320C(10,20,30) chips are the best (IMHO). There is also a large collection of TMS320 programs and discussion associated with audio filters and other DSP stuff. As far as a DSP chip with stuff already in it, I don't know of any. You must write a program, assemble and program the chip.

For assembly, TASM is a freeware assembler that handles the 320 in addition to other popular uPs. I believe the EEPROM version of the TMS320 can be adapted to a 27c256 or simular EEPROM programmer. If you really want to get into it, TI offers some development kits with already assembled boards and PC software to plug and play you programs for about $100 if I remember correctly.

Hope this helps

Mike:

The only thing I've heard of in terms of reproducing valve effects with semiconductor equivalents has been in the music business. In that case, musicians want to duplicate the harmonic characteristics and compression of tubes. A man named Eric Pritchard had built a device the do just that. However most of his tubes are geared toward audio, particlarly the medium mu tubes like 12ax7s and at7s. He may have some 6L6 or EL34 type tubes.

This probably doesn't help, but if so, mail me and I can get you in touch with Mr. Pritchard.

1413. VHF LO Parasitic--common?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-25 00:00:00 UTC
From: Zack Lau <zlau@arrl.org>
Message-ID: <313100EA.2CE5@arrl.org>
Source record: 107041

I recently noticed a low level parasitic
on a VHF crystal oscillator based on the
no-tune designs. Seems that if the
transistors have enough gain at audio
frequencies, the parallel inductor that tunes
out the crystal's shunt capacitance can form
an audio feedback path.

The cure is simple--add a small value capacitor
in series to block the audio signal, yet pass the
desired VHF signal.

The spur is easier to see if the oscillator is
multiplied by a large number--with a 24 times
multiplier the +/- 930 Hz spurs were about 60 dB
down.

I wonder if other people have noticed similar
problems? Maybe with similar circuits in more
critical applications where the spurs might be
a real problem?

Jeff, when you say the 12UA7 is "just fine", does this mean you checked it with a tube tester? If you did use a tube tester, was it a dynamic transconductance type (Military TV-7, Hickok 538, etc.) or the old GOOD-?-BAD style emission tester so popular in Radio Shack stores 20 years ago? If your 12AU7 has low transconductance in either triode section, you may not have enough differential gain to get full scale deflection on the meter.

> Double checked the wiring - it's correct, with no apperent
> cold solder joints. Correct components in place.

> I wired this myself recently, and just cant "calibrate" the
> meter.

I don't think Heath has made any VTVM kit for some years now. Assuming your kit sat unbuilt on someone's shelf for a long time, there's a slight chance that the fixed resistors used on the plate and cathode sides of the 12AU7 may have gone out of tolerance. A quick check w/ a friend's ohmmeter should be able to check this possibility out.

> Anyone know of any mods / errata on this VTVM? it
> 's the wide one with the large meter. The box pivots in a
> "U" shaped mounting bracket.

I'm personally not aware of any errata w/ your VTVM...I'd think it unlikely though, as the circuitry in your meter has gotta be almost identical w/ what's in the IM-18 I built over 20 years ago.

FWIW there have been a few aftermarket mods for the Heath and other similar topology VTVMs from other manufacturers, most notably the battery eliminator circuits intended to replace the D cell w/ a regulated 1.5 volt DC source. Heath for a time in the '70s offered a solid state conversion kit for their VTVMs as well; this kit consisted of two custom modules which replaced the 6AL5 & 12AU7, along w/ a resistor mod to the diode bleeder string.

> Probe is fine. 1.5V voltage source fine. This is stupid, but
> just can't get it to calibrate!

Oh, one last thing - have you checked the various voltages in the VTVM
against the values printed on the schematic?

It really depends on the application you are planning in your tranceiver. I use the Ti Tms320C50 DSK for some voice applications but it is crippled by the slow sample rate analog interface. It is priced at $99.00 and includes a simple assembler and debugger. Although the price is fair the Motorola 56002EVM is a better deal at about $150.00. This is a 24 bit processor running at 50Mhz with the Crystal semi. analog interface. It samples up to 48khz opposed to 19khz (I think for the Ti). It comes with a nice assembler with a lot of internal functions and the Domain Tech. Debugger. I have sent requests for help to both companies and only got answers to them from Motorola. The Motorola is also stereo which probably won't effect your application. The Ti's interface with the host computer is a very simple one and not nearly as nice as the 56002EVM. Ti does have an EVM for the C50 also but I don't think it will compete in price with the 56002 because I got a $100.00 coupon toward it with the dsk and you normally don't get a 100 dollar coupon for a 150 dollar item.

The Analog Devices starter kit is also priced low but when I checked out their dsp products you had to buy the reference books from a 3'rd party and Ti and Motorola books are free for the asking.

1420. Homebrew earphone - Mike

I want to use my 2-meter HT while motorcycle mobile. I also wear a full face helmet. The helmet speaker/microphone conversions are pretty pricey. I've seen ads for earphones that work as mikes (also expensive). Seems like a good do-it-yourself project. Does anyone know how to homebrew an earphone-mike that will work under the helmet?

Thanks and 73

>ka8ddz
LAter today I will try to Email the VGA pinout for a
HD(high density)DB15. Sadly, you are going to run into e problem that
stoped me when I was given an IBM PS1. VGA horizontal starts out at
about twice the horizontal of CGA. CGA is 15750HZ and VGA is 31,500Hz.
Then there is the fun of vertical. CGA is 60.0Hz, while VGA runs from
60 to 70 hz, with the sync polarity changing again depending on mode.
Super VGA has the same pin out as VGA, but, H freq runs from 35,370
up to as high as 60,800. I am a TV Engineer and aster frying several
CGA(actually monochrome green and ambers)monitors, I just gave up an
scrounged up a VGA monitor.
Good Luck
The figures I quated are from a 'PC Hardware' handbook, in the subsection
on Video Standards. I have seen slightly different figures in some
IBM documentation once, but, if memory serves correctly, they all
are withen a few percent of each other.

Hi Mark:

I used to ride and had a Bell full face, I used a simple electret mike element glued into the chin portion of the helment, the speaker used was a simple 2" flat style I picked up at a hamfest. I did have to dig out a little of the cushion inside the helmet.

The most unique portion however was a differential circuit made which took the input from another mike element mounted on the side of the helmet just under the lip. With motor noise comming into both elements the differential circuit only passed my voice to the rig (Well not 100% obviously) but WOW what a difference! Without it there was too much engine noise to have a decent QSO.

The rest was just simple switching, I ran the PTT to a snap action micro-switch near the horn. Hope this gives you some ideas. Good Luck

The TI chip is good, but I think the Analog Devices chipset is
even better, and the development kit is $89. (As a bonus, this
chipset is used on some soundcards for the PC, which is really
convienent if you're doing a demodulator for digital data or
an audio spectrum analyzer or FAX or SSTV or whatever, and will
be interfacing to a PC anyway.)

Yeah, you have to buy the books, but they're *good*. I've got the
TI books and the AD books, and for a beginner in DSP, the AD books
are much better, worth the cost IMHO. I also think the AD chipset
is easier to program than the TI (though this may be more a matter
of style rather than substance). And the fact that you can buy PC
soundcards with the AD chipset on board makes them a tempting target
for demodulators, FAX, SSTV, audio spectrum analyzers, etc.

I haven't dabbled with the Motorola chips yet, so I haven't formed
an opinion about them other than to note that they seem to appear
mostly in high end (high cost) products. I'm not sure what that
means.

Elendir (elendir@enst.fr) wrote:

: I barely have the choice. I cannot place a pre-amp before the filter,
: and any loss will affect the noise figure. And outputing 10 W...

Vince,

Yes, you would certainly like to filter as early as possible. However, don't be *too* concerned about loss. On the receive side you are no doubt going to have a *system* noise temperature >= 3 dB because of your antenna pointing toward 290 degree terra firma. Therefor even if you use a .5 dB NF preamp, you will not significantly improve system performance. This also means that you are not as sensitive to a loss as if you actually had a .5 dB NF system.

I'm not suggesting that loss is unimportant but only that if it is fairly low below 1-2 dB, it probably will not have much impact on receive. Relaxing the loss requirments might help the filter design somewhat.

: I have done it. 3 should do the job (3 cavities). But the Q of a single
: rod cannot reach 1000 ?

I think you might get an unloaded Q even higher than that with rods but it probably won't compare to what you can get from a cavity until the rod and enclosure size approaches that of the cavity.

: The diplexer should be used for a repeater. It would perhaps be the
: first 23 cm repeater in France, and it would be multimode (FM, BLU).

This sounds like a good project. There was a similar multimode repeater (translator) in the San Francisco area several years ago but I think it did not get too much use. Hopefully you will have a site which can help generate more activity. 23 cm is a great band.

1427. Re: Tunnel diodes: are they any good? If so, any circuits out there?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-26 00:00:00 UTC
From: "Tom V. Pfaffenbach" <tvpfaffe@mail.delcoelect.com>
Message-ID: <4gslam$l8r@kocrsv08.delcoelect.com>
Source record: 107055

Tunnel Diodes demonstrate negative resistance as the forward voltage increases. Although they can be designed for sizeable currents, the power level is limited by the low (typically tenths of a volt) level at which the quantum tunneling effect is demonstrated. Hewlett Packard used tunnel diodes for UHF/SHF oscillators and low-level amplifiers in some instruments 3 decades ago, but the Gunn diode and small geometry devices fill most applications today.

The quantum tunneling effect, like magnetic polarization, is probabilistically instantaneous and has no upper frequency limit. To demonstrate the effect, connect the diode to parallel resonant circuit having d.c. continuity and bias the device into the forward region. In the negative resistance region, oscillations will begin, and sustain.

> 73, Tim
> ka8ddz
>
You didn't say which brand laptop you were using, but most manuals include pin out information in the back of the manual. In any case, my Zeos has the following pinout and it should be standard since all the monitors work interchangably.

pin1 Red signal
pin2 Green signal
pin3 Blue signal
pin4 MS2
pin5 Ground
pin6 R ground
pin7 G ground
pin8 B ground
pin9 reserved
pin10 ground
pin11 MS0
pin12 MS1
pin13 Horizontal sync
pin14 Vertical sync
pin15 not used

MS0 - MS2 are inputs to the computer provided by the display to indicate what type of display is connected. I don't know the codes off hand. But the signals, I think, are simply open or grounded.

Also as you can see there is no simple composite video, or combined intensity signal. Unless one of the MS codes makes the display go into a monochrome mode, you will have to pick one of the colors as your output (probably green).

Hope this is a start, but you'll hopefully get a few more clues somewhere else.

The standard technique for double sided boards is to tape both the top
and bottom films (transfer films with pattern on them) to a piece of
pcb material so that the pattern on the films is off the edge of pcb
material.. When taping the second film onto the pcb material
carefully align the two layers. Then simply slide the pcb material
that you want to etch between the two films and butt upto the other
piece of material. For extra safety in handling, you can then tape
the films to the work piece. This method works well for photo
exposure but should work equally well for dry transfer.

I'm looking to build a QRP CW transceiver preferably for 20m. Any reccomendations for a good kit for a first time builder. I can solder OK and probably manage fairly fine tracks but don't have a barrage of test equipment (except a good multimeter and an old 'scope which I'm pretty inexperienced at using).

I'd like something reasonably challenging but not to difficult to align with rudimentary gear which doesn't cost an arm and leg (and of course which will work VP9 on 1milliwatt at sunspot cycle low !!).

Message-ID: <825368159.4254@ndavison.demon.co.uk>
Source record: 107063

Hi,

Can somebody explain to me exactly what is meant by necessary bandwidth and how it is calculated, or is it just another way of expressing the conventional 3dB bandwidth?.

My understanding is that it is the necessary bandwidth required to enable satisfactory reception of a modulated signal. If this is so then is there an equation to calculate it?.

Thanks

Nigel

Try Mouser Electronics (1-800-346-6873). They sell 2.5 mh chokes,
similar to the J.W. Miller 4600 series. They cost $2.53 @ quanities
of one, and have no minimum order.

Good luck with the rig, I am building a 2e26 rig for 80m, maybe
we'll cross wires.

I have not seen this phenomena, but it is very likely with high multiplication ratios to see a component at the crystal fundamental frequency. This can be annoying also. I once had to add a high Q resonant filter after a VCXO source at 425 MHz to keep the fundamental component from getting into a wideband modulator.

| Hi,
|
| Freq is 77 Khz (easy enough, it's called DCF77).
| Take a look at some Elektuur (or whatever it's called in your national
| language if there is an edition), you should be able to find
| more info.
| I have 2 clocks (one analog other digital) running on DCF77,
| nice gadget makrr are CITIZEN and JUNGHANS.
| There a lot of clocks available quite cheap from german company.
| Also interface for PC (and Mac ?).
| Hope it help,
| Thierry
```

hello all,

Am I right, the frequency is 77.5kHz (just for those who want to listen to it with a standard receiver). Its range is minimum 1500km around Frankfurt/Main (Germany). Some even expect 3000km, but shure this depends on the quality of the receiver.

The signal delivers time and frequency standards. Time is transmitted bit by bit with a signal level attenuation each second, (0=100ms duration of the attenuation, 1=200ms [maybe inverted?]). To identify the zero second pulse the preceding 59th second is not pulsed. This data stream is really easy to handle with any microprocessor. The frequency standard is the 77.5kHz signal itself, it has an accuracy of some 10e-12 or so. Its sometimes difficulty to handle as the european television system's fith harmonic of the line frequency is very near to it (78.125kHz).

A lot of commerical products are available here in Germany. As mentioned by Thierry a lot of wall watches (even in the range of DM 25,- from supermarkets, so cheaper than conventional crystal controlled systems), alarm clocks (in the range between DM 20,- and DM 50,-) and also hand watches (a little more expensive).

There are also some homebrew shops which offer kits for DCF77 reception. A wide variety is offered by Conrad Electronics, so e.g. the inside of an arm watch, about 30mm dia and 4mm high (app. DM 30,-) to include in your own products (I have one replacing my broken clock in the motorcylce), a lot of digital receivers to interface to computers and more.

As far as I know the there are two free software products which are able to sychronize your PC, one comes from Germany and one from Switzerland (Sorry, do not know more now, but I have both at home). Both are a small (1k) TSR which receive digital inputs at any bit at any selectable port (e.g. a free bit at your mouse interface or gameport) and synchronizes the PC time as soos as a valid time was received. For the reception you can take one of the receiver kits mentioned above, I also successed in converting a DM 20,- alarm clock into a continous, PC powered receiver. (In fact, even if most of these clocks use ferrite antennas abt. 2cm long 4mm dia they really work beautyful besides PCs).

I use one to set the clock in my packet radio mailbox DB0KCP, another one is used to synchronize my Meteosat receptions. Soon we will also use one for the power switch of DB0FAI, a 1kW ERP high power beacon, which is operated by DL5MCG and me. I wrote software routines for a decoding on a 8751 microprocessor, noting easier than that...

So thats some information about standard time and frequency reception in central Europe. Hope to enjoy!

Does anyone out there have any experience performing packet communication
using a DSP design? (or else know of anyone who has)
I am currently trying to develop a DSP system to run packet, and I'm
wondering what kind of modem algorithms would be best.
Ideally, I would use a sound card, but right now, I'm just messing with
stand-alone DSP systems.
Looks like I'm biased towards the Analog Devices. After comparing the
architecture with the TI, I think it would be a lot easier to use the AD.
This is for a school project, so I am not just riding a "Wouldn't it be nice to"
cloud. I really have to build one.

Direct email seems to be the best way to contact me, but feel free to respond
to this thread.

: then is there an equation to calculate it?.
:

Nigel

I suppose the term might be construed to mean "how much spectrum a particular modulated signal occupies" using a 3 dB-down or 26 dB-down or some other measure but my normal understanding of it would relate to how much spectrum is necessary for a given signalling rate (baud).

The Nyquist bandwidth deals with how much spectrum is required for a particular signalling rate but the *information* bandwidth depends upon S/N as described by Shannon.

See my ARRL conference paper:

ftp://col.hp.com/hamradio/packet/n6gn/arrlcnc/cnc.html

and select the paper "Physical Layer Considerations in building an Amateur Radio Network" if you would like more details.

My books say that it is the bandwidth where the signal energy
has fallen 22 db from peak, or alternately, the bandwidth that
contains 99% of the signal energy of the emission, whichever is
greater.

>with a zener diode.
>
>What type of capacitor and zener diode do I need to get and where can I
>get it?
>
>CraigIvey@aol.com
>
The capacitors you can get from Newark but you will have to deal with a
minimum order (I believe around $25). You should be able to pick up
the caps at a local electronic parts dealer if you have one in your area.
You might also be able to pick up the 3 volt zener there too. I did have
one question, what type of container do you have your FM-10 in? If you
have it in the plastic one that Ramsey supplies it helps but if it is in
a metal box and the antenna is brought out thru a connector and mounted
away from other metal objects (and humans-they tend to cause possible
detuning) that might help. Other items to note would be if you are using
batteries or a regulated power supply.
I have a friend I built one of these for and he is using the Ramsey supplied
case, a regulated power supply and has mounted on a shelf. He never turns
the unit off and has had no problems with keeping the unit stable. In fact
I have not reset it for him in over a year now.

Hi there. The Decameter radio bursts do not stay on a particular frequency. They are quite broad banded and move in frequency as time goes on. 22 Mhz is a good place to look, but it also has some broadcast stations on when the ionosphere is refractive to those freqencies. It is best heard on a broad band AM shortwave receiver with a directional antenna (like a Yagi or a loop) pointed at Jupiter. The emissions are very irregular, and seem to be most often observed when the moon IO is in certain positions around the planet.

Ocean State Electronics has the 4666 in their catalog, priced at $4.30
each. They don't show the 4652, but you might call them and see if
they carry it.

They also carry the Miller 70F- series of RF chokes, priced from $1.10
to $3.55 each, depending on inductance.

Linux is not a multithreaded OS, though there are ports of pthreads to
support threaded programming and I believe Linus is working on some
more native threading things in the kernel.

You can hook an interrupt in Linux by simply writing a kernel driver.
It's also been made very easy to write kernel drivers since the
loadable kernel module support has matured a great deal.

This is an interesting coincidence that this topic came up...I was
just starting to look into what it would take to write such a driver.

Hi Scott, there was a mod floating around a couple of years ago for a
mod to convert a particular Cybernet 40 channel SSB chassis (AKA the
infamous PLL02A chassis) to 6 meters by a group out of Australia.
I did 2 of these and it does work however it isn't without quirks.
ie.. USB and LSB become inverted because of low side injection instead
of the normal high side, clarifier works in reverse ect...
The mixing scheme of these radios is such that if you mess around with
the post mixer filtering you can get the sum of the mix rather than the
difference which puts you around 48 MHz (the difference puts you
on 27 MHz.). A small crystal change will put you onto 6M !
You have to be prepared to pull out several coils and remove some turns
on them as well as some capacitor substitutions in the front end and
TX RF amp. It gets pretty involved and I would say that the CB would end
up as a basket case unless you are confident with your RF knowledge and
skills along with the ability to follow the mod directions very closely.
I will see if I can find it here and e-mail it to you if you're
interested.

Regards...

>micro-switch near the horn. Hope this gives you some ideas. Good Luck

Years ago I ran a Honda twin with a 2m and 220mhz mobile. I took the
starter button wires, ran them to a 3P3T switch, and ran one
side to the starter, the other side to the radio. The switch was
mounted by the right mirror on a small bracket that I made out of
cheap angle iron. For a microphone I mounted a electret cartridge in the
chin piece foam on a Bell clone helmet, and for received audio I
had an earphone. Make sure your radio unhooks the built in mic cartridge
when the external in plugged in - some don't.
For the antenna I glued a length of enameled wire to the edge of the
fairing windscreen. Later on I put a Larsen motorcycle antenna
(1/2 wave - no ground plane) on a saddlebag top. 2m on the left, 220mhz
on the right.

The Weak Signal Challenge - 1 Year, No Winner

For the last year, I have sponsored a weak signal contest from my web page (http://www.webcom.com/~af9y/). Hundreds have attempted to extract the call of this weak Morse code signal using various signal processing techniques. So far, all have failed. I know it is possible to extract the call letters using a combination of signal processing and the "ears" of a well trained operator.

I am now increasing the prize to $100 for the first correct identification of the calling station. I believe the winner will have to break new ground in signal processing techniques. I've made available a text list of all possible calls to neutralize any recognition advantage that an experienced operator would have.

The challenge is a one minute digitized recording of a weak moonbounce signal. The Morse code signal is just above the noise but is strong enough to allow copy of my call letters (AF9Y) near the middle of the one minute period. The mystery station is sending a simple repeat of his call and my call. The characters "DE" may or may not be between the two calls.

The file is called unkn422.wav and is available from:

http://www.webcom.com/~af9y

Additional information is available in the web page.

>hi-power to be 1.5KW).So, if I understand well, the degree of mismatch you want
>your ATU to handle is also a critical factor in the voltage tolerance.

Yes the mismatch makes a significant difference and it is not just the SWR
that matters, but what the impedance is that causes the SWR. A tuner might
handle a much higher mismatch in one area of the Smith chart than another.

> Any advice from the gurus on how to pick the capacitors? Is there data in the
> literature I can look it up?

If you can find or afford them, vacuum capacitors are the way to go. The
voltage ratings are high, there are no sliding contacts and the minimum
capacitances are low.

> Another thing: can capacitors with the same spacing have different voltage
> rating? I have seen adverts of 2mm spacing capacitors with ratings of 4KV and
> 7.8KV. It doesn't look reasonable.

It's possible. It can depend on the thickness of the plates and their finish.
Thicker plates with radiused and polished surfaces will withstand higher
voltage before breakdown than will thin stamped plates with rough, sharp
surfaces and edges. The insulation supporting the fixed plates is a factor
too.

You must not forget the inductor either. Most of the loss in a well-designed
tuner will occur here.

>

Scott,

Many years ago, one of the ham magazines (I don't remember which mag or what issue) published an article on converting the popular HyGain 40-channel CB boards to 6m FM. These boards were the same ones that thousands of hams bought to convert to 10m FM in the late 1970s and early 1980s, back when 10m had propagation.

I personally converted *dozens* of these boards to 10m FM (and made a small fortune doing it). They're easy to work on, straight-forward in design, and easy to come by.

I'm fairly sure the magazine in question was "73". Find someone who has a complete library of them going back to about 1977. Consult the December issue of each year for the Annual Index. Search there for the article. It is possible that this article was in QST or Ham Radio, but I'm leaning toward "73".

Good luck! 73 de KC5NG

1477. Direct conversion

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-29 00:00:00 UTC
From: clifto@indep1.chi.il.us
Message-ID: <DnJxHL.H1@indep1.chi.il.us>
Source record: 107005

I've decided to try to design a MW broadcast-band receiver (at least in part to bolster my meager analog design skills), and it occurred to me that I might like to try using direct conversion. What are the issues, tradeoffs, etc. that might affect that decision?

My main objectives are high sensitivity, low noise and distortion, and selectivity as good as I can reasonably get it (in that order). I was thinking that direct conversion can help me avoid a lot of problems with LO nonlinearity and distortion products, etc. I also remember that many of the reasons it didn't fall into general consumer use were the expense of multi-gang tuning capacitors (which I bypass with nice, cheap varactors), the design tradeoffs in trying to get wide bandwidth out of tube circuits (of course I'll be using transistors and/or ICs) and some vaguely-remembered problems with detector design (I like the idea of synchronous detection; comments on that welcome as well).

If I remember right, there's also the problem with superhet that the optimal amount of LO injection is very different for weak signals than for strong ones, and that trying to vary it causes problems with dynamic range considerations. I'd like this thing to perform as well with the 50KW locals as with the 5KW station in Moose Jaw.

1478. Can anyone ID these IF amps?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-02-29 00:00:00 UTC
From: bob@waterw.COM
Message-ID: <9602292038.AA08525@water.waterw.com>
Source record: 107006

Last night I picked up some IF amps at our club's White Elephant sale. They have RCA part numbers, but none of the retired RCA guys at the meeting had any idea what they were for. Markings are:

LOG IF AMPLIFIER
RHG ELECTRONICS LAB (15286)
MODEL NO. ICL60G23EA
RCA CORP P/N 5616449-5

The connectors are labeled: IF IN, -15V, RET, +15V, TP1, VID 1, VID 2, TP2.

The price was right (25 cents each), so it was worth the gamble that they might be something interesting.

Any info about specifications would be appreciated!

Tnx

I have built the MFJ 8100 SW Receiver KIT and am very impressed with its performance.
It is a "regenerative" receiver ... about as basic as you can get and still get Shortwave.
Takes about 2-4 nites to build, runs off a 9V battery into a set of Walkman-type headphones. Covers a lot of HAM and SW Broadcast bands.

>How much trouble would it be to modify an amp made for use between 3-30 MHz,
>for use on, say...75 meters? Is it possible or economically feasible?

Well, the amp already covers 75 meters, IE 3.75-4.0 MHz, so no modifications
should be required. You'd probably (certainly!) want to make sure there's
a low pass filter on the output to suppress 2nd, 3rd, 4th, 5th, etc harmonics
in the output of the amplifier. Suitable filters are shown in the ARRL
Handbook.

It might be a good idea to modify the amplifier to improve its efficiency
on 75 meters, but the nature of any such mod would depend on the circuit
design used for the broadband amp. Likely it uses ferrite transformers,
and the reactance of the output transformer may be a bit lacking at the
low end of its design range. You might get better results by changing the
ferrite mix, or increasing the number of turns, primary and secondary,
on the transformer. RF bypass capacitors also might be marginal at the
low end of the range, and might benefit from having additional capacitance
placed in parallel with them. Careful here though, you could get into a
motorboating situation if you get carried away.

Tune to 60 kHz for WWVB. It's an combined pulse width amplitude/phase
modulation at a 1 Hz baud rate. Details of the modulation are in
"Reference Data for (Radio) Engineers", the book published by Sams.
Or from the bulletin published by NIST.

Since there's only one transmitter for the US in Colorado, signal
strength is nowhere near what the europeans can expect from their German
or UK (at Rugby, also on 60 kHz) transmissions.

Looks like a log amp made by RHG for RCA. The model number is probably RHG's
and the P/N is RCA's drawing number (possibly USN). Without a drawing, you
probably don't have a prayer in learning about the innards. Use'em for parts.

There may not be anything to modify although, you might want a low pass
or band pass at the output to keep down the harmonics.

I wrote source code for a simple keyer for the PIC16C54 (18 pin DIP).
It has paddle selected speed and a synthesized 833 Hz sine wave output
for code practice or sidetone. E-mail me if you want a copy, as I have
no IP. de KJ5WA

1488. Re: Direct conversion

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-01 00:00:00 UTC
From: clifto@indep1.chi.il.us
Message-ID: <DnKMs4.25J@indep1.chi.il.us>
Source record: 107016

I flat out BLEW it. I don't know where my mind was, but I did not want
to talk about direct conversion; considering that I can't remember the
correct term for what I am thinking about even after a few hours have
passed, I assume my brain needs Beano.

What I was trying to convey is that I want to create a receiver that
will amplify and filter the heck out of the RF, then run that straight
into a detector.

The rest still applies.

In article <DnJxHL.H1@indep1.chi.il.us> clifto@indep1.chi.il.us (Clifton T. Sharp) writes:
:I've decided to try to design a MW broadcast-band receiver (at least in
:part to bolster my meager analog design skills), and it occurred to me
:that I might like to try using direct conversion. What are the issues,
:tradeoffs, etc. that might affect that decision?
:
:My main objectives are high sensitivity, low noise and distortion,
:and selectivity as good as I can reasonably get it (in that order).
:I was thinking that direct conversion can help me avoid a lot of
:problems with LO nonlinearity and distortion products, etc. I also
:remember that many of the reasons it didn't fall into general consumer
:use were the expense of multi-gang tuning capacitors (which I bypass
:with nice, cheap varactors), the design tradeoffs in trying to get wide
:bandwidth out of tube circuits (of course I'll be using transistors
:and/or ICs) and some vaguely-remembered problems with detector design
:(I like the idea of synchronous detection; comments on that welcome
:as well).
:
:If I remember right, there's also the problem with superhet that the
:optimal amount of LO injection is very different for weak signals than
:for strong ones, and that trying to vary it causes problems with
:dynamic range considerations. I'd like this thing to perform as well
:with the 50KW locals as with the 5KW station in Moose Jaw.

1. 75 meters is between 3-30 MHZ
2. Look in YOUR various Radio Amateur books/ study manuals etc. for how
basic tuned circuits and components work together.
3. Decide if you have the skill, time, and ability to make it worth your while.

While it's not an exceptional device, it's hard to beat an HP ATF-21186 for price. $2.00 each. The only downside I've found is minimum order size. $50 from Pennstock. I don't know of a dual-gate of hand. Somebody will.

Oops, I just saw you're in the UK so maybe this doesn't help.

Cheers, Wes -- N7WS

Gerhardt G. Herbst II, is the patent holder for "Cold Spot Module".
This product is for sale to an individual or manufacturer.

The "Cold Spot Module" is used to effectively reduce the operating
temperature of integrated circuits such as computer CPUs to maintain
reliability under extreme operating conditions. This module is protected
under a U.S. Utility Patent issued in October of 1995. A Utility patent
provides the strongest protection under U.S. law.

An independent North American Market Study was done on the product and the
potential market has been identified.

The product has not yet been introduced to the general public but is referenced
in the U.S. Patent catalog which is posted periodically. For an on-line reference
refer to:

http://www.uspto.gov

Search on Patent Number: 5457342

The title abstract is: Integrated circuit cooling apparatus

Note: A search on just the patent number will bring up the details.

Exclusive rights can be purchased reasonably with negotiable license term.

For further information, contact Gerhardt G. Herbst II.

1492. RHG IF Amp - Can someone provide specs?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-01 00:00:00 UTC
From: bob@waterw.com
Message-ID: <4h75p8$3ak@sea.waterw.com>
Source record: 107020

At a local white elephant sale, I picked up four IF amps for a dollar... not much of a waste if I can't get the specs for them, but I was hoping someone could provide some clues. The parts are marked as follows:

LOG IF AMPLIFIER
RHG ELECTRONICS LAB (115286)
MODEL NO. ICL60G23EA
RCA CORP P/N 5616449-5

The input/output pins are: IF IN, -15V, RET, +15V, TP1, VID 1, VID 2, TP2. There are two pots labeled SLOPE and OFFSET.

Any info/help would be appreciated!

acssb radios are being marketed in the us by SEA electronics. They are trunked, as the previous reply stated. The LTR format seems to be the standard. There are several companies setting up regional systems that are linked via spread spectrum. My shop is in the process of building up a acssb repeater. Neat stuff, indeed. 73, Will

>Well: I checked my RHG catalog and they don't list the ICL60G23EA.
Thier part numbers usually show the first two digits being IF freq.(ie
60=60MHz) and second two digits(23) are the band width in MHz. The part
number start at ICLL. No ICL. Typical number would be ICLL6020. The
outputs are shown as IF in, IF out, and video1. They also have a Pot. for
offset adjustment. You can give RHG a call at 516 242-1100. This info is
from thier 1988 Catalog. They are a division of Adams Russell.
Hope this helps. 73 WB6IQD Tom dunnt@starbase1.caltech.edu

Try Aspen Electronics (0181 868 1311), or for small quantities try
Mainline Electronics (0116 277 7648).

The RSGB Microwave Components Service (G3WDG and G4KGC) might be able to
recommend a good equivalent, and probably supply it too.

>(The same circuit uses a CF300 dual-gate GaAs tetrode. How much does this

Same circuit as which? Surely not an LNC?

CF300s are "priceless" - becoming very hard to get!

: Nope, don't even consider it.

Are you joking or how do you figure?

there are/were wide band amps for 3-30 mHz although the CB boom just
about wiped them out. There are plans in various places for such
wideband amps.

75 meters is right in the low end of the range for the amp mentioned
(3.8-40 mHz)

It's being marketed (very successfully) in the UK by Securicor as
'LINEAR MODULATION'

I toured the factory (near Bath, UK) last year and saw a large number
of radios being soak tested - these were badged with another vendor's
name, and were destined for Chicago.

1500. ? Duplexer 2m/70cm

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-01 00:00:00 UTC
From: guenter.koellner@oen.siemens.DE
Message-ID: <313727FB@SmtpGate.Oen1.Oen.Siemens.De>
Source record: 107028

Hello folks,

our latest german ham newspaper, cq-DL 03/96, shows a duplexer for 2m/70cm.
It is refrenced to an article in "amateur radio".

The circuit seems to be very easy. Starting from the common connector it
uses quarter wave lines to the 70cm and 2m port each, where always a LC
notch filter cuts off the unwanted band (for example, from the common to the
2m port: quarter wave for 70cm and a LC for 70cm).

The 70cm notch is built of 67nH and 3pF, the 2m is built of 12pF and 200nH.
But thats all they showed. They did not show the winding datas for the
coils!

So, my question: Does anyone of you know the original article in "amateur
radio"? If so, can you provide me the coil winding datas?

And for specialists: Does anyone have experience with expanding it to 23cm?
I think it there is a possibility to add a 23cm circuit at the 70cm port,
isn't it?

However, since you need as much Q as possible, you probably
want to use waveguide filters, dispensing with most of the
resonator rods. You might want to save one rod to feed the
input of the FET preamp. A rather challenging project, but
certainly possible--Zack.

Collins Collectors Association
Frequently Asked Questions (FAQ)
(Updated 3/96)

What is the Collins Collectors Association?

The Collins Collectors Association (CCA) is a not for profit organization dedicated to supporting Amateur Radio operators who share the opinion that Collins Radio made the very finest amateur communications equipment available. The Associations root's can be traced back to February of 1988 when Bill Wheeler, KDEW organized a 20 meter NET made up of 17 like minded Collins users. That small group grew to over 1,200 by 1993.

The purpose of the Association is to:

-Promote the care and use of Collins Amateur Radio Equipment
-Preserve the history and lore of Collins Radio Equipment
-Provide an information archive for Collins Radio Equipment

What are the benefits of belonging to the CCA?

For the active Collins user, belonging to the CCA can be extremely beneficial. Our membership has a vast collection of printed matter relating to Collins Radio including both technical and promotional material. A simple verbal request on any one of our 3 nets for technical information or a service part can result in half a dozen or more offers of help. We also have an informal group of extremely capable
"Senior Technical Staff Advisors" who work on a volunteer basis to help members solve what can be complicated technical problems encountered in Collins amateur products.

An added benefit, members receive our quarterly newsletter, The Signal.
They also receive a handsome, numbered membership certificate suitable

for framing. The CCA offers other Collins related items available exclusively to members such as extremely high quality QSL cards, CCA name badges, tee shirts and other memorabilia.

Because the CCA stands for and promotes gentlemanly and amateur-like operation, there is a real opportunity to share in quality fellowship with other CCA members. You may even meet a few of our members who were employed by Collins Radio and were instrumental in designing, producing, marketing and supporting Collins Radio equipment. Some of those members are Warren Bruene, W5OLY who designed, among other

things, the 30S-1 linear amplifier and 30K-1 transmitter and was Collins most tenured employee having started in 1939 and retired in 1984.
Member Dennis Day was one of the prime engineers on the 75S-3 and Gene Senti was the designer of the KWM-2, 30L-1 and KWS-1. We are proud to have these fine gentleman who have both directly and indirectly contributed much to amateur radio.

For those who may wish to add to a station or collection, the CCA attracts an elaborate and reliable network of equipment sellers as well as members who may be interested in selling or trading their own gear.

How does one become a member of the Collins Collectors Association?

Any person who has an interest in Collins Radio is welcome to join us.

Annual dues are $15 for those living in the US and Canada and $18 elsewhere. Again, this includes the membership certificate and our quarterly newsletter, The Signal.

Mail your remittence in US funds to:

The Collins Collectors Association
PO Box 840924
Pembroke Pines, FL 33084-0924
E-Mail: collins@exis.net

We support a 2-way exchange of information with our membership and encourage everyone to share their experiences. The Association offers

the best benefit and value to all when members share their Collins related experiences and situations.

How do I stay in touch with and participate in the CCA?

Besides our quarterly newsletter, the CCA currently has 3 affiliated nets which meet weekly. They are as follows:

The 20M net meets every Sunday on 14263 at 2000UTC. This is our formal,
directed net which usually has the greatest number of check-ins. It is dedicated to both technical subjects and the listing of equipment buy/sell opportunities.

The CCA also supports two weekly 75M nets. The first meets Tuesday nights on 3805 at 0100 UTC and the second meets Thursday nights on 3875 also at 0100 UTC. The 75M nets are designed to be informal with open discussions and the least amount of structure possible.

Such a conversion is pretty straight-forward;
just plug in new crystals and re-tune.

Ian,
There is something 'weird' with your address. I sent you a 3 page written response and everytime I fire up my Ultimail, it refuses your address. I don't know what to tell you, except I'm able to send mail and replys to just about everybody else.

Hello James.

From Antique Radio Classified Magazine, (P.O. Box 2, Carlisle, MA 01741),
there is an ad from Midco for crystal set parts, plans, kits and books.
Catalog is $1.00. Address is P.O. Box 2288, Hollywood, Fla, 33022.

I used to build the coils on oatmeal boxes. Also fun to experiment with
razor blade edges as a detector.

Good Luck with the projects.

Rod

I wonder how Mr Herbst slipped this one past the prior art
investigation? This technology has been around since the early 70's -
at least. For example, IBM and Amdahl main frames made extensive use
of it.

1511. TRF etc.

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-04 00:00:00 UTC
From: clifto@indep1.chi.il.us
Message-ID: <Dnr815.wn@indep1.chi.il.us>
Source record: 106939

Okay, maybe the TRF wasn't such a good idea. However, the idea came about because I've heard so much over the years about LO noise, LO distortion, excessive or insufficient LO injection, mixer noise, mixer distortion (as far as I understand it, a mixer won't work without distortion, although I suppose the PC term is "nonlinearity" :-), etc.

Yes, it's easy to put together a receiver using something like an NE602, or any one of the nifty chips out there. A TDA1072 has a sensitivity of 15 uV for 26 dB S/N. But I won't LEARN anything by doing it, as I've done enough home projects and kits over the years to make it little more than an afternoon's busywork.

So, what about local oscillators and mixers, and the problems inherent in them, and how to solve them? (I'm reading up; but experiences are good to hear, and I don't have access to the very latest stuff, either.)

True, but I thought those shortcomings were related to tube design
and to the cost of multigang variable capacitors; neither is a problem
with semiconductors (though coils are a consideration). Are there any
shortcomings I've missed?

Another question arises: is it practical to use gyrators in RF tuned
circuits? In all these years, I've found about four pages (literally)
of reading about gyrators, two in a magazine and two in a datasheet.
The applications shown were audio low-pass filtering.

Paul,

That's a very blatent claim you make. This patent went through with only one need for clarification from the PTO. Obviously know one else sought such a patent which is evidence by the PTO issuing me patent # 5457342.

Those companies you mention have devices that are similar with respect to cooling only if you care to follow the patents mentioned on my abstract. However, NONE have developed the device I have NOR do they have a patent on such a device. As such, I am the sole owner to pursue development of this product or companies under infringement.

What I am wondering is what this has anything to do with amateur radio antennas, homebrew, space, etc.? The point is that this, and the preceding posts were made to the amateur radio news groups.

Cooling of microprocessors, and your grandstanding of being awarded a patent are of no interest to me or in any way pertinent to my interest in amateur radio. And that is why the newsgroup(s) have those titles.

If you are looking for invetors, get a clue and do it somewhere else.

If you are simply so proud of yourself for being awarded a patent for what appears to be anothers work, then HIP HIP HOORAY for you! Now grow up and go away.

> clifto@indep1.chi.il.us --The Third Law of Reality

Probably the biggest fault of the TRF is the decreasing selectivity
as the operating frequency increases. For example, in the am broadcast
band at 1000 kc, a 10 kc bandwidth signal is 1% of the operating
frequency, and the next station up the band at 1010 kc is just about
1% away. Not too difficult to construct a trf receiver to reduce the
interference from the adjacent station.

Move up to 10,000 kc and the percentage drops to 0.1% and so on
up in frequency. Separating signals becomes more difficult. To overcome
this more stages are added in the trf to narrow the band width. As you
noted the multi-section variable capacitor can be eliminated
with vari-caps but the frequency tracking problem is still there.

Getting several stages to change frequency together is a challenge
as anyone who has built them can tell you. Above 15,000 kc or so
the inevitable mis-tracking nullifies the added stages selectivity.
I have built them and can testify to that! And by the way, inductors
have instability problems too (mainly thermally induced).

The superheterodyne does its' selectivity and amplification chores
at a fixed frequency where all the best techniques can be applied.

Having too much time on my hands, I went and looked at your patent.
The first part of the patent describes the exact CCD cooling method
used for years by Santa Barbara Instruments (and others) for cooling
CCDs. Your novel claim seems to be an IC cooler that is retrofitted to
an existing, uncooled IC.

Gary,

: Vincent, silver plating allows you to lower the *insertion* loss of
: the system while adding another cavity will *increase* the insertion
: loss of the system. They aren't alternative paths to the same solution.

I agree.
Is it really that significant ?

What is the improvement in the insertion loss between a normal copper
cavity and a sliver-plated one ?

>
>I agree.
>Is it really that significant ?

Perhaps. There are a number of other factors that come into play, including system topology, so it's difficult to give a hard and fast answer.

>What is the improvement in the insertion loss between a normal copper
>cavity and a sliver-plated one ?

To the *system*, it could range from 0.5 db up to 2.0 db (or even more). In most cases, 0.5 db isn't significant, but 2.0 db almost always is. As I said, there are a lot of other factors at play here. If the cavity is rather small, and has high circulating currents, silver plating makes a substantial difference. If the cavity is large, the difference is less significant because the sheet resistance is lower, or looked at another way, the current density per square centimeter is lower in the larger cavity, so the I^2R loss is less.

But in any case, if, because the unloaded Q of the plain copper cavity is lower than a silver plated one, you have to use an additional cavity in the system to get the required isolation, then the insertion loss of that extra cavity would count toward additional system loss. This may be more significant than just the I^2R loss difference between a plain cavity and one that is silver plated. This is particularly important if the additional cavity is a pass cavity. If it is a notch cavity, the difference will be much less significant.

If I were building a notch duplexer, I wouldn't worry much about silver plating. I'd just use 6 notch cans instead of 4. But if I were building a duplexer using pass cavities, I'd give them a good rubdown with Cool Amp so that I could use only 4 instead of 6, and I'd make those 4 bigger than notch cavities too. That should cut system insertion loss by at least 33%, and I'd call that significant.

Simple. He reinvented it first!

1526. Re: Can anyone ID these IF amps?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-05 00:00:00 UTC
From: ccurtis@avionics.ITt.COM
Message-ID: <313DD4E3@avint4.avionics.itt.com>
Source record: 106954

Bob,

These IF log amps (detectors) cost around $700 back when there were new. The part you mention is a "special" made for RCA by RHG. One video output is a DC level proportional to the log of the amplitude of the IF input. The output approximately ranges from about 100 mV to 2 volts with input amplitudes of -60 dbm to +10 dbm. The output is a linear function of the input power in dBm. The unit responds to signals 60 Mhz +/- 23 Mhz in frequency. The other video output is a 'limited video' output for use in detecting the simple absence or presence of on input (think of it as a logic level output).

You could make a nice, sensitive power meter for the 6 meter band with one of these units. Just apply DC power to the unit and connect a DC voltmeter to the video output. Apply a low level, 60 Mhz +/- 23 Mhz signal to the IF input. The voltmeter will indicate the power level of the applied IF. You could calibrate it against a known
power meter for use as a stable, wide dynamic range, accurate power measuring
device.

From: bob@waterw.COM (Bob Applegate)
Subject: Can anyone ID these IF amps?

Last night I picked up some IF amps at our club's White Elephant sale. They have RCA part numbers, but none of the retired RCA guys at the meeting had any idea what they were for. Markings are:

LOG IF AMPLIFIER
RHG ELECTRONICS LAB (15286)
MODEL NO. ICL60G23EA
RCA CORP P/N 5616449-5

The connectors are labeled: IF IN, -15V, RET, +15V, TP1, VID 1, VID 2, TP2.

The price was right (25 cents each), so it was worth the gamble that they might be something interesting.

Any info about specifications would be appreciated!

Tnx

As a scout merit badge counselor, I am in need of kit addresses for the kids.

Seems many of them are gone. Rainbow too expensive, and ramsey somewhat limited. Looking for the older stuff, such as receivers, strobelites, etc.

any ideas?

thanks

jserocki@wwa.com

How thick a layer of silver do you want? I have a 'silver polish' which claims to silver plate not only silver (hence avoiding loss of silver when you polish) but also 'silver plates' metals like copper. I've tried it on coins, keys, etc, and it certainly coats the copper in a 'silver' layer, and I have no reason not to believe that the layer is actually silver. However, it's obviously not very thick.

This leads to another (important) point :

At 145 MHz, how thick must the plating be ? More than 10 microns, I guess.
The skin effect is not that important.
Next, what about silver oxydation ?

Where copper has a resistivity of 1.0, silver is 0.9. Therefore,Unless it is
done properly (and regular plater's- used only to doing ornamental plating
may well not know); silver plating copper coils and cavities may actually
increase their loss.

> sell small quantities?

Ferrite beads act only as a lossy inductor, and therefore their single pole "filter" response curve probably won't give you the attenuation you need for a spurious signal only 2 octaves away, depending on relative amplitudes.

Typically, one would use an active or passive elliptical filter, positioning the zero's that are present in the stopband right on the frequency causing troubles.

One might get away with better lead dress and shielded wire for the different modules...

Good luck, Bob T.

Alan M. Horowitz (horowitz@nosc.mil) penned:
: I shouldn't throw away my QST's after reading them, I guess!

: I need a ferrite bead that will keep a 25-khz spurious square-wave (it's
: a legitimate clock signal in another board) from entering my receiver's
: a-to-d. The wanted analog signal is a voice channel centered around 6 khz.

: Which is the proper formulation of ferrite? Who are the vendors who will
: sell small quantities?

Those freqs seem a bit low for ferrites. For audio freqs I would guess
that some big electrolytics across the power busses would help. And the
grounding of the different circuits has to be checked to see if there
might be ground loops. If you can detect a sq wave with a scope across
the opposite ends of a ground then there is current in the ground that
should be rerouted to another point.

>I had no trouble getting it to work on Linux.

Greetings. Correction, it's now at:

ftp://ftp.uni-ulm.de/pub/pcb/current

and all you need is the pcb-xxxx.tar.gz file... it has all the
samples, packages, and READMEs in it (I mention this because
they are also provided in the above directory and want to save
people extra downloads). I too have had no problems running it.
It's not as "spiffy" as some of the limited-demos that some
firms put out for DOS/Windoze but it does the deed.

I'm fiddling with a free PCB list (like my free spcie list, see URL:
http://www.paranoia.com/~filipg/HTML/FAQ/BODY/F_Free_Spice.html) but
I only have a few listed now... Please let me know if you know of
any other PCB packages that are demo or Free.

Take care.

Source record: 106966

Supposedly the biggest advantage to silver plating is AFTER it ages and begins to oxidize.... while corroded copper will normally require periodic disassembly and cleaning, silver oxidation is still highly conductive. (One reference: ARRL "FM and Repeaters: A 2 Meter Duplexer", page 110. Also the old ARRL VHF manual mentions the relative merits of silver plating.

In 1982 I put a Peltier Cooler on a 8087 coprocessor in an IBM computer in an effort to speed up the clock. I had a PC board made and along with schematics and documentation. This progressed into modules for 80287's. In fact I hold the record for the highest speed attained using a 80287 in an IBM AT computer by cooling the 80287 down to -50 deg C.

I therefore have prior documented art on this invention and demand all royaties should be sent to me. <grin>

>and cavities may actually increase their loss.

I thought the point to silver plating was that silver oxide conducts
much better than copper oxide? In other words, a silver-plated
surface will greatly outperform the copper after the material ages.

Norm,

Old ARRL Handbooks are great for what you want as are old issues of QST.
Many libraries have back issues of QST on microfilm. I am currently
completing a cw transmitter featured in the March 1971 issue of QST. Hope
this helps.

Lessee, my reference lists copper as 1.724e-6 ohm-cm resistivity, and
silver as 1.62e-6 ohm-cm. Normalizing to copper=1 makes sliver 0.94, not
even as good as 0.9. OK, that's for DC, but things get more complicated at
RF. If you want to compare copper and (solid) silver in exactly the same
mechanical configuration, including surface finish, and the material is
several skin depths thick, then you have to account for the fact that the
skin depth is not as great in the more conductive silver, and that means
the gain is NOT 1:0.94, it is only the square root of that or 1:0.97. In
other words, the best you stand to gain is 3 percent, assuming you can keep
either the copper or the silver free of dissipative tarnish. Of course a
coating that isn't several skin depths thick won't even do that much good.

I'm just saying I think Drew is right on, even more so.

HAMMARLUND AIR VARIABLE CAPACITORS

::::::::::::::::::::

TYPE APC

Compact, hi-quality variables. Isolantite base. Screwdriver
or hex-wrench adjust.

APC-25 3.0 - 25 mmf 9 available
APC-140 6.7 - 140 mmf 2 "

TYPE MAPC

Midget padding, trimming and general purpose capacitors similar
type APC but smaller. Ideal for small space applications. Gap
.0135 inch. Rotors and stators are nickle-plated brass.
Nickle-plated beryllium copper wiper contact. Tapped (4-40
thread) brass studs in Steatite base permit mounting without
grounding rotor. Tested at 600 volts rms, 60 cps. Slotted
shafts for screwdriver or hex wrench.

MAPC-75 3.9 - 75 mmf 6 available
MAPC-25 2.6 - 25 mmf 17 "

TYPE ???

Identical in size and shape to the type APC, but have military
part number. Rotors and stators are silver plated (tarnished).
Please note that capacitance ranges and values for this
particular group are APPROXIMATE, subject to the accuracy
of my RLC tester.

922-0004-00 2.5 - 30 mmf 9 available
CA-290 3.5 - 60 mmf 7 "

::::::::::::::::::::::

The are all NOS units and are in excellent condition (mil types are silver
tarnished).

$45 + shipping for the entire group (50 caps)

Older copies of the ARRL Handbook are great for learning basic tube theory and schematic symbols. They also have many construction articles covering transmitters, receivers and miscellaneous tube-type equipment.

For repairs and troubleshooting, I'd check the local library. Unless they've brought their entire collection up to date, they'll probably have just what you're looking for.

Antique Electronic Supply lists a product in their catalog for do-it-yourself electroplating. Says it uses current from any 3 or 6 volt battery. The silver product cost $12.35 and the plating brush that connects to the negative side of your battery is $1.35. BTW the brass product is $2.75, the copper is $2.75 and nickel is $5.60.

Gaerhardt-

I think some of us have jumped to the erroneous conclusion that your
invention duplicates prior art. On the other hand, your statements do not
clearly show how it is different from prior art.

You are looking for investors to finance development of a product that on
the surface, appears to be old technology. I suggest you revise your
"sales pitch", so that it is clear that your invention is (a) new, and (b)
of commercial value. In other words, why would one want to use your
invention instead of existing spot-cooling techniques?

This seems like a good idea. How about going for a rig based upon
modern semiconductor components (such as complete IF strips), but only
providing the facilities available on older valve rigs such as the
KW2000 and the FT101? - ie, basic radio without the CBer/DXer/Contester
gimmicks. What would have been a major project 20 years ago could now
be within the grasp of most hams. The only advance in the direction of
very modern electronics that I would suggest is to consider the use
of DDS to reduce the essentially difficult bits that still remain; that
of creating a stable free-running VFO together with crystal mixers.
The older style rigs, I believe, still sell well to those starting out
on radio.

There's a diode you can clip, I *think* it's D51 - I better go check; don't cut anything yet! - which gives general coverage TX, 1.5-33 MHz. You have to take the thing apart quite a ways to get to it. With that mod, and a battery-box to feed variable DC to the ALC (which is a jack on the back) the thing becomes quite a useful signal generator/local oscillator for all sorts of homebrew projects, not to mention QRP operation... you can drive the ALC way down to making the output in the milliwatt range. I will post the circuit if there is interest. It's a 9V battery, a 100 K pot, and two or three other resistors.

I know of no comparable way to increase the 6m TX coverage, or to fill in the RX gap between 33 and 46.2 MHz. If somebody does, I'd like to learn them.

I'd also like to hear from anyone who (reversibly!) disables their IC-726's final amp, and brings out the low-level signal for transverter use. I'd like to do this to mine too, but don't know where the best place to bring out the signal and to switch the final-amp bias lines are.

Finally, a few QSTs ago had a two-part series on IC 725 mods, including an RF speech compressor, better audio filtering, improved AGC turnaround, and a few other things... the articles claimed the IC 726 was electrically identical in all places covered by these mods, but I haven't done any of them. Some looked quite useful!

>I'm just saying I think Drew is right on, even more so.

Perhaps, or perhaps not. Since a lot of RF conductors are silver
plated, and silver isn't cheap, it seems a bit hard to swallow
that those hard headed manufacturing engineers are doing it just
for decoration, especially since most of that silver plate is never
seen by the customer. Even Detroit doesn't chrome plate the *inside*
of its engines without a sound technical reason.

So perhaps we're overlooking a factor here. I think Jack may have
given us a clue. Lets see what the oxides of the two metals look
like. Right away we notice something striking. CuO has a magnetic
susceptability of +267 while AgO has a magnetic susceptability of
-19. Hmmm... now that seems to put us on the footing where we found
ourselves when discussing steel wire for antennas a few months back.
(By way of comparison, the magnetic susceptability of FeO is 293.)
The much higher magnetic susceptability of CuO means the skin depth
will be *very* thin, and net skin resistivity very high. Meanwhile,
the negative value for AgO means that the skin depth will be greater
than anticipated, so the margin between the two for RF seems much
greater than 3%.

Figures are from the CRC Handbook, 47th edition, table starting
on page E-103.

As with steel versus copper for antenna wires, we have to look
beyond DC resistance to find out which material is better suited
to the task. It turns out that oxidized copper is almost as bad
as oxidized steel as an RF conductor. That shouldn't surprise
us, corroded coax (from water wicking into the braid) is a very
lossy medium. Now we know why.

Gary

Duplicating in discretes what you can do in chips only gives you more
practice *soldering*. If you study how the chip works, you'll learn
as much as you will studying the discrete equivalent, if not more.
Unless you just particularly like extra wiring and soldering, there's
no real reason not to use a chip, except maybe if you think you are
a better designer than the chip designer.

The latter is possible, if your design goals are different from those
of the chip designer, of course. I advocate working at the highest level
of integration that meets your performance goals. I'd suggest that's mostly
at the chip level today, with a few discrete odds and ends thrown in to
satisfy some unique features you may desire, or to act as glue bits to
tie chips together.

Instead of a 6 transistor radio, I'd suggest you'll often do better
with a 600 transistor radio, with those transistors housed in a couple
of chips. Especially for circuitry calling for matched devices, you'll
do better using transistors on the same substrate than you will trying
to use discrete devices (a Gilbert cell mixer is one such application).

These sentences seem to imply that it is always better to use an
IC for a particular function rather than a circuit composed of
discretes. This is not true. ICs offer some significant advantages
over discrete designs, particularly very compact size and highly
repeatable behavior. Also, monolithic semiconductors tend to have
excellent matching, a specific advantage for a balanced mixer.
However, these advantages may not be so important for a particular
project. Passive diode mixers still offer some of the best overall
performance you're going to see in a mixer, and even a fairly cheap
diode DBM has better strong signal performance than an NE602.
Granted, the NE602 mixer has gain *and* an oscillator on chip,
but this isn't necessarily a compelling reason to select the single
chip over the dozen components. It really depends on the application.

>Unless you just particularly like extra wiring and soldering, there's
>no real reason not to use a chip, except maybe if you think you are
>a better designer than the chip designer.

The chip designer operates inside a set of tradeoffs, just like the
discrete designer. A chip may be intended for a particular application,
and less than optimal in another application where a fairly simply
discrete circuit works better. Two of the major reasons for using
an IC is to reduce size and improve manufacturability, which can
adversely impact the performance of the circuit in comparison to
a discrete circuit where size, manufacturability or even power
consumption aren't issues.

>The latter is possible, if your design goals are different from those
>of the chip designer, of course. I advocate working at the highest level

>tie chips together.

Now, after having appeared to disagree with you, I'll emphatically
agree with this paragraph. Figure out what functionality and performance
is desired, then examine all available solutions. My disagreement
is the notion that chips are always going to be better; this kind of
prejudice is what causes people to use a $3 chip where a $.10 transistor
would do a better job.

>Instead of a 6 transistor radio, I'd suggest you'll often do better
>with a 600 transistor radio, with those transistors housed in a couple

Another example of where an IC is the obvious answer is an FM
receiver IF strip. Even if all you ever look at is the Motorola
databook, there are several excellent options there. But, a receiver
front end is a different story. The kinds of chips that make sense
in a receiver front end are quad hot carrier diodes and quad DMOS FETs.

You are unlikely to find any beads that are effective at such low
frequencies. However, regular multi-turn inductors and bypass caps
should do the job for you if the interference is, in fact, being
conducted as opposed to radiated.

I have several books by Abraham Marcus on servicing tube-era radios.
They are superb, and are relatively common on the used book market,
since every radio repair shop had one on the shelf in the back room up
through the Sixties. I want to say the title is something like RADIO
SERVICING although the book isn't here at the office and I may not be
recalling it perfectly. It went through numerous revisions and I have
three of them.

RCA's RADIOTRON DESIGNERS MANUAL (or something close to that) is
another standard worth snagging when you see it on the used market.
It was published from the Thirties through the Fifties. I have two
editions of that as well, and there's nothing like it for
tube-oriented design.

As for tube homebrewing, hit the hamfest circuit and start
accumulating QSTs from the Fifties and Sixties. You can't do better
than that for good projects.

You might also subscribe to ELECTRIC RADIO magazine, which has been
publishing nice tube projects in the last year or two.

Good luck with it and let us know how you do.

>want.

Also make sure the color coat isn't lacquer-based or it may cause the
crackle paint to lift off the surface. To identify lacquer, look for
nitrocellulose as one of the ingredients. A dry time of less than
a half hour usually also indicates lacquer (or one of its cousins).

As a designer of RF equipment for several manufacturers, including commercial equipment, I can tell you why these manufacturers silver plate coils.

They do it because it looks and solders better, or because of marketing. After all, some things are just "supposed to be silver plated".

If the goal was to prevent conductivity loss from corrosion, the coil would be coated with a very thin dielectric. It's cheaper and works just as well. In the real world, there is no worthwhile improvement in coil Q from silver plating.

As I said earlier, it's like mag wheels with wide tires on a Toyota. 99% show.

Contacts are another story, however.

From: vinyn1vc@aol.com
Message-ID: <4hsn4r$c08@newsbf02.news.aol.com>
Source record: 106852

I tried the Hot carrier diode approach, specifcally the 1N5711 priced at 55 cents. It actually worked up to around 7 GHZ and would have gone higher I think. The sensitiviy seemed greater than the orignal mixer. However when sweeping it I did see a lot of peaks and valleys or resonances. How ever I don't have it properly packaged inside of the mixer, that circular "T" piece is not in there. Maybe that will help I will try it next.

Thanks for the suggestion,

Viny Coppola N1VC

I would futher suggest that silver plate on "CLEAN" copper could be very thin as it only has to protect the copper from corrosion. Silver on other metals such as brass should probably be as thick as the skin depth for the frequency in use.

Having investigated this patent, it appears to cover a very, very
narrow area of widely used prior art. I particular it is a device that
can be added to an existing IC in an existing circuit to cool a single
IC. The
method of coolling (peltier junction, heat sink and fan) has been used
in many different fields - so there is nothing new here.

As far as it practical value, you would have to have room in the
device enclosure to add the add-on cooler, an method of
expelling the removed heat from the enclosure and some source of power

for the add-on
device(s). The needed additional room sounds sgnificant with the heat sink and fan. For each IC you needed to cool, you would need a seperate device.

It also appears that this patent is not even a very good replication of the
prior art of IC cooling. In the abstract it does not mention any method of regulating the IC being cooled. A peltier device will lower the temp of it host device by a certain level from the ambiant temperature. This means that as the ambiant temperature changes, so will the temperature of the cooled device. Regulation sets the device temperature at something less then the full cooling capability of the peltier junction and then monitors the temperature and regulates the peliter junction to insure the
cooled device stays at a constant temperature.

If the cooler is unregulated, then wild swings in ambiant temperature will produce wild swings in the device temperature.

In my humble opinion, this patented device is not worth much. It does not do the job well. There is so much prior art in this field that one could create a slightly different device and not be in conflict with this patent and would probably do a better job.

Sometimes we get a little lost in the physics. The easiest thing to do is examine some real world coils, I've done that with new coils and silver plating makes no worthwhile change in unloaded Q. If the goal is to prevent surface resistance shange, the coil can be lightly clearcoated or tinned. The amateur user will never notice the performance difference, unless it's a sliding or moving contact.

I hope people don't start thinking siver plating makes a big difference, copper clad steel is a bad RF conductor, or a steel slug will increase the inductance of a coil at high frequencies.

#1004 100 WATT (PEP) WALKIE TALKIE

Make any walkie talkie get out with the power of the big guys. This tiny
power converter requires less than 1 watt of driving power to
create a 100 watt PEP output. Even so, the power consumption is less
than 2 watts of energy, so it will operate for long periods on its
small battery pack. Note: This device was designed for use in remote
areas of the world and is not approved by the FCC for use on
the citizens band.

PLANS ONLY KIT #1004 POK . . . . . .
$19.95

So it will just make the other 98 with its good looks.... Didn't some
one write a law about conservation of energy or some other nonsense...
On the other hand, if you hold a 100W ant 6 inches from your head you
could come up with all kinds of neat plans.
==========

#1005 POCKET PAGER

This tiny pocket paging system was designed for rapid signaling of any
person carrying a similar device up to 3000 miles away.
(Shades of Napolean Solo, "Open channel D";) Not a talking system,but
rather a signaling or paging type system. IC circuitry
transmits hundreds of miles in less than 10 milliseconds.

PLANS ONLY KIT #1005 POK . . . . . .
$19.95

At least the radio waves from this one don't travel faster than the
speed of light. (I didn't do the math, just making a guess!!)

Just thought everyone might enjoy reading these!!!!!!

The above is true!!!

To answer the question.....

Antennas are electric circuits of a special kind. In ordinary circuits,
the dimensions of coils, capacitors and connections usually are small
compared with the wavelength that corresponds to the frequency in use.
When this is the case, most of the electromagnetic energy stays in the
circuit itself, and is either used up in performing useful work or is
converted into heat. But when the dimensions of wiring or components
become appreciable compared with the wavelength, some of the energy
escapes by radiation in the form of electromagnetic waves. When the
circuit is intentionally designed so that the major portion of the
energy is radiated, the circuit is an antenna.
(1991 ARRL Antenna Book Ch2 first paragraph)

What actually "leaves" the ant is a Magnetic field.
the only stupid question is one that dosen't get asked!

That ^ is good! However, to answer the poor guy's original question,
a voltage does NOT leave the antenna. The voltage IN the antenna induces an
electroMAGNETIC wave which leaves the antenna.

When using Schottky (Hot Carrier) diodes in a mixer, you can improve performance by matching the diode barrier height (Vf @ 1 ma.) to the L.O. power level. HP, MA-COM, Metelics and others make a line of diodes with different barrier heights low, medium, high, extra high.

Have Fun,
Brooke

Tom,

Thanks for the clarification! The "magnetic susceptibility" referred to in my physics book is apparently more correctly "relative magnetic susceptibility" since it's dimensionless -- that's what threw me off. With the definition you've used, the data in the CRC book make sense.

Roy Lewallen, W7EL

1601. Help with identifying coax.

I have some high quality double-shielded Teflon dielectric coax for which I would like to get some precision N connectors. The coax is unmarked however, and the connector suppliers I've contacted tell me they need a UG number or other identifier inorder to provide the correct connector. Can anyone help identify this cable? The outer sheath is a very slick plastic (HMW polyethelene?), lavender in color, about 0.275" diameter. The silver-plated braided shield beneath is about 0.190 diameter, and is separated from the spiral wound flat inner shield (O.D. 0.150") by a thin layer of wrapped teflon. The stranded central conductor, inside more wrapped teflon, is silver-plated, 0.056" O.D. (15 guage), and contains 19 28 or 29 gauge strands.

Any body got a field guide to coax?

Thanks in advance for all responses.

Cheers,

Jon

>Has anyone made 5 Volt PC switching power supply modification to 13.8 Volt ?
>thanks info, Danilo +
Your first problem will be the transformer its turns ratio is for 5 volts
while it will probably go to 6 or 7 13.8 will require a ratio change.
Next problem output cap is probably a 5 volt working cap need to change
that diodes may have a piv problem you probably need more inductance in
the filter choke

In short I'm a power supply engineer and I'd hate to try and do that in
my home shop its probably not worth the effort unless you just want to
learn about switching power supplies

gud luck

>the antenna and going anywhere, just the "effect" rippling through the
>universe that we hang names on.

This is a really nice intuitive explanation, but somehow I find it
lacking (as I also find the explanation in the Antenna Book lacking).
For example, the Antenna Book seems to be saying that an antenna needs
to be a large fraction of a wavelength in size to radiate well, but
then we have magnetic loops like the Isoloop which are tiny fractions
of a wavelength yet radiate well. And I'm not sure we can say fields
are imaginary when EM radiation can have mass (solar sails, Special
Relativity, etc). I have a hard time calling anything with mass imaginary.
And QM says the electron itself is a field (of a different sort).
It all rather defies intuition.

I was reading an article the other day that goes back to an older
concept, that of waves in the aether. The concept of aether was
discarded at the turn of the century (thanks to Michelson-Morley)
but it has arisen again in the context of the vacuum energy. It

seems modern theory (and experiment, Casmir Effect) show that the vacuum isn't empty. Rather it is seething with enormous energy fluctuations (and in fact that the universe itself is just a temporary fluctuation in the vacuum energy via E=MC^2).

EM propagation is then viewed as just a temporary organization of the vacuum fluctuations in a wave-like propagation. In other words, EM radiation temporarily folds, spindles, and mutilates the vacuum through which it travels in a way described (at least to a first approximation) by Maxwell and the Poynting vector.

At a deeper level, the vacuum energy is also spacetime, and is thus warped by gravitational fields, nicely explaining how an EM wave can be bent by gravity, and obversely how an EM "photon" can have mass. C then becomes a fundamental property of the vacuum, and not something unique to EM radiation. It also explains the attenuation of EM radiation by matter. Since matter is just a peculiar type of fluctuation in the vacuum energy, it can be represented geometrically as a sort of "distance", and the characteristic inverse square law can be applied to that "distance" to explain attenuation.

This all boggles the mind, and appears to have some rather incredible implications, especially when considered in the context of certain QM attributes of action at a distance, dead/not dead cats, and the like.

Yeah, thanks, Tom. Looks like that was a blind alley. I still think
there must be some reason other than decoration that the *inside*
of cavities are silver plated. No one is going to see it, so I still
think it's put there for a functional purpose, we just haven't found
it yet.

>sold that I kit, I would appreciate having the information

Just go to Pep Boys or Northern Handyman (or even Sears) and get a
good auto battery charger with dual modes. They aren't expensive,
and they'll do what's needed.

The way the charger determines which mode to be in is by monitoring
the current draw. As the battery approaches full charge at 14.2-14.4
volts, the current will drop. When it drops past a set point, the
charger switches taps on the transformer (usually a relay), and
delivers the "float" voltage of 13.8 volts indefinitely.

An easy way to sample the charge current is with a fractional ohm
resistor in series with one of the battery leads. A comparator is
wired across the resistor and when the voltage falls below the
set point, the comparator changes state and drives the relay.
(Alternatively the charger could use a linear voltage regulator
and use the comparator to change its set point, but that costs
more for a high amp charger.)

Gee, I remember the CK722 as being made by Raytheon and in a silver metal can that was of a rounded rectangular shape (kinda like a small IF transformer) with three thin wire leads from a white insulator.

I know there's one around here SOMEPLACE but, of course, I can't find it. Not that I would part with it anyway, but I could at least verify the physical appearance.

FOR IMMEDIATE RELEASE
CONTACT: RICHARD D. EUTSLER, SR.
March 11, 1996
Liberty News Service - 802-485-4170

F.C.C. Refuses to License Low Power Broadcasters

Radio Police Raid Small Broadcaster Instead

Prepared to use force if necessary, federal police arrived at 8 AM on March 7, 1996, to remove a small radio transmitter from the home of A.L. Kobres, a long-time radio enthusiast. The transmitter had been in use for about one year on 96.7 FM and served the community of Lutz, Florida. It was being used to provide information on topics such as home schooling, natural medicine, organic gardening, constitutional law, politics, and POW/MIA issues. Patriotic music was interposed with the programming. The predominately live "talk show" format originated from various points all over America and was downlinked by satellite for broadcast. Several programs originated nearby in the Tampa Bay area. The transmitter power level was less than 50 watts. The range was about 6 miles. All transmissions were identified as those of Lutz Community Radio and a telephone number was given. There were no complaints. Calls from listeners were of a constructive/positive nature. The station operated non-commercially, being funded entirely at Kobres' expense.

The FCC will not license a station to operate with less than 100 watts. The cost to obtain a license can run well over $100,000.

The FCC came to Kobres' home initially on November 3, 1995, in an attempt to compel him to terminate the broadcasts. The FCC justified the demand based on a complaint by a licensed station which supposedly suffered because some of its listeners were switching over to the small Lutz station. Kobres was not warned that the FCC might return and take his equipment by force. On 12/1/95 Kobres wrote to Ralph M. Barlow, the Engineer in Charge of the Tampa FCC office in an effort to inform Barlow that the Communications Act of 1934, which created the FCC, was actually founded upon an economic emergency declared on March 9, 1933, and that the justification for the emergency (economics) cannot be found in the Constitution. Kobres provided Barlow supporting evidence of his assertions. The evidence consisted of Dr. Eugene Schroder's research, which remains undisputed. Both audio tapes and printed material were provided. Kobres also informed Barlow that he was exercising his right to free speech on the airwaves because licensed broadcasters had generally failed to inform the public of many important issues affecting the future of America.

Kobres said that the U.S. Supreme Court has affirmed that the use of the airwaves is the modern day equivalent to the use of the printing press - a fundamental right. He also asked Barlow how the FCC can expect Lutz Community Radio to possess a license when no license for small broadcasters is made available in the first place. Kobres never received a reply to his inquiry from the FCC.

Interestingly, Kobres had previously been on friendly terms with the Tampa FCC office as he had installed most of their antennas and computer equipment.

Last time I checked, the photon (the thing that EM fields are made
of) was still massless (well, the most recent experiment that I found
had its mass as less than 10**-27 eV). It is correct to say that the
EM field carries momentum, which is usually thought of as something
(like a ball) travelling with a particular velocity, but field theory
depends actually on the photon being massless. Of course, other fields
can be thought of as having mass (mediated by massive particles like the
Z and W) but the EM field as it stands doesn't carry any mass. However,
the field is measurable, so it's hard now to call the field "imaginary".

>I was reading an article the other day that goes back to an older

This whole problem with the vacuum is quite an old one and is a subject of
current debate among physicists.

>The silver product cost $12.35 and the plating brush that
>connects to the negative side of your battery is $1.35.

For what it is worth, I've used a similar product consisting of a brush "pen" which held 2 AA cells and a ground return lead out the top.The plating material comes from a loop of silver wire within the brush. Dip the brush in an electrolyte solution and "paint" on the silver...

While slow, it does a credible job on flat or simple surfaces (such as 1/2" copper water pipe for 2m cavities). Trying to plate a 3.5" diameter 30t coil of 1/8" tubing after forming the coil was another story. Trying to plate the inside of some homemade waveguide or other irregular / inaccessible shape is probably impossible.

>voltages.

Hi Pigdog,

This is one of the big effects of the universe. Whenever an electron is accelerated or moved, all the other electrons in the universe try to re-adjust to the change. So the electron does not really go anywhere, the "effect" does.

The rate at which this effect moves through the universe is called the speed of light. We use imaginary things called "fields" to explain this "effect", electric fields and magnetic fields. We can't make one field vary without producing the other field, we can't stop one varying field without stopping the other. Neat, huh? ALL antennas are ELECTROMAGNETIC.

When the little electrons "accelerate" back and forth in the antenna, the electromagnetic fields we use to explain the effects we observe are "produced". Actually, there really isn't even a "wave" or anything leaving the antenna and going anywhere, just the "effect" rippling through the universe that we hang names on.

On a less serious note, if you take 100-200 micrograms of that stuff after your signature, you may be able to see these waves rippling through the universe like tiny golden fishes (Cream, from Swabalar 1969) !
;-)

1624. VHF Converter Alignment

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-12 00:00:00 UTC
From: k2ek@aol.com
Message-ID: <4i4v2q$rqo@newsbf02.news.aol.com>
Source record: 106902

I am trying to resurrect an old Janel 144CF 2m converter I picked up at a flea some time ago. I suspect its alignment was seriously screwed up by prior owner's diddling (images, instability, etc). Tuning consists of 3 tuned circuits before and after the mixer stage, with a single tuned circuit at RF amp input. The LO seems fine.

Lacking a swept signal generator, NF meter etc, I am wondering if it is possible to simply stagger tune the circuits - say at 144, 144.5 and 145MHz - using an HT with 30db pad (about 1mW output) for a signal source and tuning for a peak reading voltmeter reading on the IF receiver's audio output?

Any suggestions will be most welcome...

>Charles

I routinely use oven drying for enamel paints, as do the auto
manufacturers for their finishes. It won't give you a wrinkle
effect unless the drying agents in the paint allow it to wrinkle.
I looked this up after the first round. Wrinkle finish paints
use *two* carefully chosen solvents with different drying times
in order to achieve the wrinkle effect. One of the solvents needs
to be very volatile, the other not.

Ordinary enamel paints may use more than one solvent too, but
normally their drying times are similar, hence no wrinkles.
It may be that the particular paint you used had solvents that
volatilized sufficiently differently when heated to achieve a
wrinkle finish, but that's not the normal way baked enamels
behave. I've found that when using Krylon I get a much
smoother finish when I bake it than if I let it dry at
room temperature.

1627. lightning detector, how?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-12 00:00:00 UTC
From: Tom Kreyche <tkreyche@well.com>
Message-ID: <4i47l1$21r@nkosi.well.com>
Source record: 106905

I just read a review of the SkyScan lightning detector. It's a hand-held 4x6 inch box which has led's which indicate lightning distances in ranges of 0-3 miles, 3-8 miles, 8-20 miles, 20-40 miles and has an indicator for severe storms. Price is $200, Automated Weather Source, 301-258-8390

The reviewer checked it out in weather service office that had doppler radar and an expensive lightning detector and found that it worked well.

I'd like to build something similar and perhaps build a dual arrangement to get crude triangulation. Anyone have any references for this type of instrument?

Obviously with a relatively low frequency radio, e.g. am broadcast band you can easily pick up lightning induced noise, but how do you translate it into distance? The audio output could easily be filtered and digitized, does amplitude translate directly into distance? What frequencies are best for lightning detection?

Thanks, Tom Kreyche KG6YJ

1628. Re: Silver Plating An Alternative?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-13 00:00:00 UTC
From: Bob Mueller <IFF161@DJUKFA11.BITNET>
Message-ID: <96073.110930IFF161@DJUKFA11.BITNET>
Source record: 106729

When I posted under the above title I was amazed at the number of email responses, well beyond the trigger level at which I promised to post a recipe. (I have come to expect no answers as that is the typical result, even when I feel certain somebody out there has the information I need!)
As I wrote before, the method is one long used by clock makers to put a silver layer on a copper or brass dial to improve the appearance. On a matt surface the dial takes on a nice white color until the power plant sulphur turns it black.
Except for the silver compound, the other ingredients can be bought in a food store. You may have trouble getting cream of tartar but I get it in England at Safeway. Try a drugstore if you fail at the food store. (my wife says it is used in some Asian cooking.)
You can buy silver cloride or make it from silver nitrate. Adding NaCl to a solution of silver nitrate will cause the cloride to form. Collect it with a filter paper. (The collection ought to be quite efficient as silver cloride has a very low solubility in water.) Wash out the salt and store the cloride in a dark place. Or prepare the cloride each time so it is fresh.
Clean your copper very well, and while it is still wet rub it with a cloth to apply a thin layer of paste of fine salt in water. Then run on the silver cloride paste (the old recipe recommended a piece the size of a marble for 10 square inches.) The copper should turn grayish and ugly with streaks and all. Then put on the cream of tartar, applied with the same cloth (Muslin, they say) where the cream of tartar is in the form of a paste in water. Rub all over and the silver should start to whiten. Keep your fingers off the surface during all the processing. Rubber gloves are good protection against contamination. Wash off the parts in the hottest water your hands will tolerate. Dry.
You ought to be able to buy solutions to do this all with less rubbing and similar bother. In either case, "homebrew, old-fashioned" or with modern solutions, you are removing a bit of copper and replacing it with some silver. I do not know how thick the layer is and the depth is limited: the removal does not proceed to arbitrary distance into the metal as the new silver protects the underlying metal. Conversely, the skin depth is not great at high frequency and the silver might be thick enough (and more than a couple skin depths is wasted silver. It would be valuable for somebody to test and post the results as to whether he observes the predicted Q-improvement when plating with some electroless method.)
Electroplating is the way to go around the limit on thickness. It is not a replacement process and thick layers can be added to the surface. But then we seem to be back to cyanide solutions and living with the slight loss of Q is better than loosing a life.
I just received word our system is going down in a few minutes so I must sign off. I plan to say a bit on copper plating (and on other metals in pass-ing) without cyanide but this message will be lost if I do not sign off. 'til

then.....
Bob

A friend of the family's (when I was a kid) worked for a paint
company and he once brought me home a 1pt can of hammertone
paint, which I promptly used on everything metal I had.

So hammertone isn't anything you do, you just paint it on.
Beyond that I have no idea.

144.955 is in the middle of the 2 meter Ham band and only
FM is used on this freq. If you have some other use for a
receiver I would suggest any used scanner. They are cheap
and will cover a large number of frequencies.

One comment on a coating to protect from oxidation...

I've only tried this on brass for cosmetic reasons, but I've had success using clear acrylic floor wax. Its cheap, may already be in your house, and has kept a brass key looking good for several years. Just wet the surface with a light coat from a paper towel or a Q-tip.

I've been thinking about trying it in an RF application but haven't done it yet.

Lee Blaske <lblaske@pclink.com> shared the following priceless pearls
of wisdom:

>It was expained to me that the Heath light green finish as found on the SB series is
>not a crackle finish. In fact, that finish is accomplished by some sort of
>spattering process using a special paint spraying nozzle. Ron Eisenbrey, who
>refinishes vintage ham gear, just finished a batch of Heath equipment. It'll
>probably be some time before he gets around to Heath again.

If I'm not mistaken (and I frequently am) we used to get a good
crackle finish by first applying enamel, waiting until it set up
tacky, then oversprayed with lacquer. Somehow the solvents in the two
varieties hated each other and got to fighting amidst the hills and
crevices of the finish.

Or something like that. Oh, the poster who said the Heath finish
wasn't crackle is correct. I believe the correct term for the Heath
finish is hammertone, and I DON'T know how to do that one easily.

Mine is made by Rayteon and is black plastic with a clear section near the leads. It cost about US $7.00 when it was new. I couldn't afford one but a frend could and he ended up giving it to me.

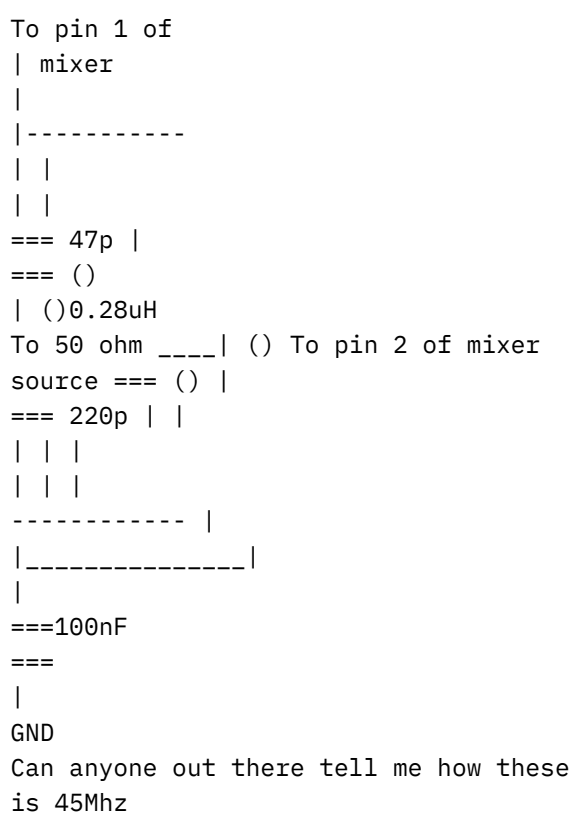
Hi there
This is to all those who know anything about impedance matching!
I have a circuit using a ne602 ic.The input impedance is is quoted
as bieng 1.5k.I have a Phillips application note (AN1993)
that uses this ic.The input to the mixer of the ic is from a 50 ohm source.
The 50 ohm source has been matched to the ic by the following circuit.



Can anyone out there tell me how these values are calculated.The frequency of interest
is 45Mhz

From: Peter Shintani <shintani@tv.sony.co.jp>
Message-ID: <4i7n69$6ji@oskgw.osk.sony.co.jp>
Source record: 106744

Hi
I bought a IC-706 and would like to build a HF/6m duplexer so
I don't have to manually switch antennas. (The IC-706 outputs HF and 6m via
one connector and I have two antennas)
Can someone provide a schematic on how to build a duplexer for Hf and 6m and
or guide me to some source that describes how to design the duplexer.
(Comet makes a commerically available duplexer but it seems a bit expensive)
By the way, I tried to build a low pass and a high pass filter to split the signal but I seemed
to get some interaction between the filters, so I don't thing designing
separate sections is the correct method to design duplexer. Each filter individually
had the correct response but when their inputs were paralleled it didn't work.
I had funny dips in the response.

I have an automation system clock that until recently resided at WGHB-AM in Farmville NC. It is a Schafer model with nixie-type display tubes. The internal workings of the clock are a fascinating mixture of electronic and mechanical mechanisms. It would be ideal for a ham or hobbyist who needs a clock for pulse creating or preprogrammed events. $150 plus shipping gets it. E-mail direct.

I don't recall a Heath with a hammertone finish (but that doesn't mean they never used it). That was the finish on old Bud boxes. It vaguely resembles a sheet of metal that has been lightly hammered with a ball peen hammer, IE a pattern of varying grey tones, thus the name. The Heaths I recall all had a textured finish, like that delivered by a roller or a "spatter" gun. BTW, I seem to recall someone here recently recomending using a roller to achieve a nice textured cabinet finish.

And I don't know how to achieve a true hammertone finish either.

I would prefer a W6PO design, it is the most flexible design I know for different sizes of tubes. There are also some statements on "symmetric and asymetric loads" caused from the anode resonator made by him that I agree to. It is really easy to be built. I am currently building one using a GS35B

tube.

By the way, I am still searching for a suiting design for a 1.5kW+ tube for 70cm. Until now I have the YL1040 design by OZ9ZI adn a 8938 design from the

"Radio Handbook". Do you know any other, maybe one using not the standard flat plate line but a cavety design as they are more known for the 23cm amps?

From: mcmahon@cad.uccb.ns.ca
Message-ID: <4i71qn$65q@News.Dal.Ca>
Source record: 106914

I just sent for a fm transmitter (Ramsey FM-10A, $35!) which I want to use to distribute stereo throughout the house and yard. With the proper antenna I was told it could potentially broadcast up to a mile - the kids are gona love this! So, I started trolling the internet to see just what the candian regulations are on fm transmissions but so far I came up empty. Can anyone here point me in the right direction? And, by the way, is this the right group to ask? I'll check back, but e-mail is better since I'm not a regular. Thanks for any help.

Early SB-series Heath gear is definitely not hammertone - it is indeed
a wrinkle finish. I can't comment on how Heath applied it, however.

Incidentally, does anyone else remember Heath selling touch-up paint
at one time for that equipment? I seem to remember being told that it
was available in a regular spray can. Yes? No?

Gordon,

AMTOR is a close relative of SITOR which conforms to CCIR recommendation 476-2 (and later revisions). The CCIR recommendations are available from ITU in Geneva. The acronym "AMTOR" was coined by Peter Martinez, G3PLX, who we can say is the father of this amateur radio mode.

Yes, there are several error correcting protocols in use. You may want to look into and retrieve our discussions of this topic on the TAPR HFSIG (HF special interest group - web page is at www.TAPR.org). If this topic excites you, also consider coming to the ARRL DCC that is planned in September this year in Seattle. You will have the opportunity to hear about these developments and contribute your own ideas.

Hope this is of interest. Feel free to e-mail me directly if you need further pointers.

The explanation I learned (admittedly many years ago) is that a photon
has zero rest mass, but that it carries a mass equivalent in its
energy, as related by the Planck Law, E=hv, and the mass energy
equivalence, E=MC^2. That may be intuitively Newtonian, but it gives
the right answer for solar sail calculations. I'm not at all sure
what you mean by "impulsion", but you seem to be implying that it
is a tensor field quantity of some sort that warps spacetime conversely
from the way it is warped by gravity. I freely admit ignorance of the
finer points of General Relativity.

It also, I think, is a side issue to the resurrection of the concept
of the vacuum energy as being the aether.

Jack et al... Heath used several color schemes over the years. My first transmitter - a DX-20 - had a medium grey wrinkle cabinet with a semi-gloss light grey fron panel. I am currently restoring a IM-18 VTVM which has a light brown or tan semi gloss front panel and darker brown "splatter" cabinet. It looks a little like semi-glass latex applied with a roller. I am also restoring a SB-610 monitor scope which is the more recent light and dark green and is definately wrinkle. A similar color scheme was used in the early 60s (Mohawk, Marauder, Warrior, etc) but they were gloss enamel for both panels and cabinets.

I too remember touch up paint being available in a spray can.

>>Has anyone made 5 Volt PC switching power supply modification to 13.8 Volt ?
>>thanks info, Danilo +

You probably can get the +12V output to go to 13.8 That will limit you to 7 amps or so. You will have to change the voltage sense resistor from the 5V out to the 12V output. Otherwise, there won't be enough energy in the core to keep the 12V up under load. Yes, also disconnect the rectifier from 5V so you don't blow up the 5V caps.

Downside is that you might find a lot of receiver birdies from the switcher. They're not all that well filtered.

: the right answer for solar sail calculations. I'm not at all sure
: what you mean by "impulsion", but you seem to be implying that it
: is a tensor field quantity of some sort that warps spacetime conversely
: from the way it is warped by gravity. I freely admit ignorance of the
: finer points of General Relativity.

Well, it is almost true. Almost because the true formula for energy
is E^2 = M^2*C^4 + P^2*C^2, simplifying to E = M*C^2 at rest.
Impulsion is P, quantity of motion.
The vector P and energy E can be in special relativity merged into
a quadrivector impulsion-energy (maybe the English word is impulse !)
that get generalized in the general relativity into a tensor field.
You mentioned the equivalence mass <> energy, thereby the metric tensor
is bound to energy, and therefore mass, by the Einstein equation.

>
> Charlie Fortner
> KF4GJQ

Charlie:
The wire wouldn't do anything because the 5/8 ant in grounded
in the mount. If you have a fiberglass car then only a 1/2 wave would
work, because you have no ground. Note: a 1/4 wave on top of the
car will work better than any antenna mounted on the trunk.

The S-AV17 is the stock amplifier in many Kenwood 2m FM mobile radios
and possibly other brands. It's a two stage bipolar transistor class-C
amplifier, so it's only suitable for FM. Be careful when mounting these
not to bend the baseplate and crack the ceramic (this seems to be the
primary mode of failure).

Another approach is to obtain a commercial mobile radio and remove the
power amplifier, harmonic filter, and T/R switch from it. Then for <$50
you'll have a 50 ohm in/out amplifier, heat sink, harmonic filter, and
half of the T/R switch. (You'll need another relay to select whether the
HT goes into the amplifier or the straight-thru receive path, but this
relay only needs to handle 200 mW of course). Most of the Motorola
models were built assuming 400 mW of drive from the exciter, so rated
output may not be obtainable with only 200 mW. (But, see below). This
project would end up quite a bit buliker than a module-based amplifier
would be.
>
>Be very careful with your T/R switch, as this amplifier has a
>lot of gain and will oscillate easily if the output is coupled
>to the input.

Very true. This is the main problem with trying to boost a 200 mW
HT signal. My C508 440 MHz amplifier had some trouble with this, I ended
up having to settle for 15W of output instead of 20, which of course is
still "noticeably better" (17 dB) than 280 mW. This is with a 4-stage

amplifier from an RCA "700" radio (early '70s vintage), and homemade reed relays.

Look in the new '96 ARRL Handbook. There's an amp just like this one.
They call it a "brick" amp. The setup includes a table for a pad you
install on the PCB that'll allow almost any drive level from .5 to 5
watts.

>Trying to plate the inside of some homemade waveguide or other irregular /
>inaccessible shape is probably impossible.

No problem! K9EEY's 'Ham Radio' article about using spent (silver-
loaded) photographic fixer solution also describes a "brush" made from
sponge wrapped around the end of a carbon rod. In this case the silver
comes from the solution rather than an internal silver anode, so the
sponge has to be dipped back into the jar at frequent intervals.

The carbon rod can be made any size and length you need. The long, slim
copper-plated carbon rods sold as arc-brazing electrodes are great for
plating the insides of tubing. Before using the rod, pare away all the
copper from the end that will contact the sponge and solution. Wrap the
rest of the copper surface tightly with tape to avoid shorts and
unwanted electrolysis of the copper. Obviously you could extend the
"handle" with any length of insulated metal tubing, to reach the bottom
of a cavity for example.

I have a cheap Rat Shack 49.830MHz transciever that I want to refit to transmit (and recieve if possible) in the cordless phone handset band (48.76MHz to 49.970MHz). The unit has two crystals in it (which I assume control freqs). One is 16.45833 (MHz or Khz?) The other is 16.610 (MHz or Khz?) .. Would it be possible to replace the crystals to change the freqs? Ideally I'd like to be able to select channel numbers (1-25). Could I use a voltage controlled oscillator or something? I'm waiting to get the service manual from rat shack, so I *may* have more details then.

Thanks A Bunch

1676. Kit QRO HF rigs...Hands Electronics RTX series?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-14 00:00:00 UTC
From: yee@mipg.upenn.edu
Message-ID: <YEE.96Mar14104036@picard.mipg.upenn.edu>
Source record: 106754

A couple of weeks ago, I posted a question about kit hf rigs.

I got a couple of pointers to Kanga US. Apparently, they are a one man operation (definitely a plus...gotta support the little guys) which distributes kits from Hands Electronics, another one man operation in Wales.

The Kanga catalog mentions the RTX 206, RTX 210 and several other kit rigs from Hands electronics. They are multiband CW/SSB kit rigs putting out 15 watts. The design of the rigs is modular and each module can be purchased separately. All together, the rigs ain't cheap but that isn't the point. Building is more fun than buying. What I find most annoying is going to do is to go hunting in multiple catalogs in search of all the parts that I need for a project. Would much rather purchase everything in one block. Besides, I do not currently know enough to design my own rig.

Anybody build these Hands Electronics rigs? How difficult are they to build? What is the performance of the finished rigs?

It occurs to me that I can build an outboard solid state amp for these rigs and bring them to the 100W class rigs. Any flaws to this idea?

Source record: 106755

Hi,
I have managed to successfully build a modem using the XR2211 and the XR2206 chips. It uses the BAYCOM software which is freely available, runs at 1200 baud, and works very well on 2m once the pots have been carefully adjusted!

I used the schematic on Jim Devenport's homepage, for building this modem. The url is

http://nis-www.lanl.gov/~jdport/emul.html

The baycom software can be found on many FTP sites. The one I used is FTP.FUNET.FI and can be found in the following directory

ftp.funet.fi/pub/ham/packet/baycom/baycom15.zip

I hope this is some help to you !

I bought my first CK722 in 1956 or 1957 (according to my increasingly vague memory). It was the rounded rectangular shape. It was the color of dryed blood (dark reddish brown) with a clear layer at the end where the three thin wire leads entered the case. It was made by Raytheon.

Personally, I never saw one that was any other color or shape.

I am not sure how you can get a copy, however, here in america is a
company called "North American Philips" a spin off of Philips of the
nederlands. They produce a general purpose replacement line of
semiconductors and a cross referance book listing tens of thousands
of original equipment part numbers. They will have the zeners you are
looking for and a way to find them using equivalent OEM part numbers.
Maybe I could get a catalog to you, or help you find what you want.
I recently used zeners for screen grid voltage stablizing. Big
surprize, Screen grid current is sometimes reverse flow back into
zeners. 73 Don KD3SH

..

Thanks to Jack for a nice posting on using polyurethane varnish. I had a brief email exchange with Jack about one issue that remains in my mind, and agreed to post it here to see if anyone has any difinitive info on it.

My concern is that polyurethane has a rather high dissipation factor. It was a little hard to find listings, but looks like about 0.05, compared with .0002 or less for polystyrene, polyethelene and Teflon. So the question is, given that it's used in a rather thin coating, does that really make any difference? Has anyone actually measured the unloaded Q of a cavity before and after coating with any type of clear coat, whether it's polyurethane or acrylic or something else?

>
>I think solar sails work because light has _momentum_

Yes indeedy, but momentun has the units of *mass* times velocity.
That's the problem. To get momentum transfer, we have to satisfy
M1*V1=M2*V2, where M1 and V1 are the sail's mass and velocity
and M2 and V2 are the photon's mass and velocity. Setting M2 to
zero yields zero momentum transfer. So we have to assign some
value of mass to M2 in order for a solar sail to work. Since
a solar sail does work, that implies light has mass (or something
equivalent to mass, in this case E=hv becomes through mass
equivalence M=E/C^2). That works too. We find, for example,
that a UV photon delivers more momentum to the sail than an
IR photon because it has greater energy, and hence greater
mass equivalence.

No, we have to satisfy p_{initial} = p_{final}.

>and M2 and V2 are the photon's mass and velocity. Setting M2 to
>zero yields zero momentum transfer. So we have to assign some

When you talk in terms of photons, you have to talk in terms of 4-vectors.
If you just wanted to talk about radition pressure, you could use the
Poynting vector.

>that a UV photon delivers more momentum to the sail than an
>IR photon because it has greater energy, and hence greater
>mass equivalence.

Your first clause is correct, but your conclusion is not sound. m1*v1=m2*v2
doesn't hold relativistically.

1696. How to test a 3cx3000 ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-03-14 00:00:00 UTC
From: paul1@wizard.ucs.sfu.CA
Message-ID: <9603141029.AA22619@wizard.ucs.sfu.ca>
Source record: 106774

Does anyone have the means of testing a 3cx3000 ? I have one kicking around in my junk box, and before I turn it into a bookend or something would like to know if it is functioning (or should I say functionable???)

I'm happy to pay shipping and a reasonable fee if necessary. I won't need it in any event as my linier plans revolve around some 4cx1000's and 4cx1500's I have as well, but knowing it is workable would be nice if I decide to sell or swap it.

cheers, Paul

Unitrode makes an ic for charging starved electrolyte (new name for gell cells) batteries.
The device requires programming resistors and a pass transistor.
Part number is UC3906N.

A microwave oven can be used to determine relative loss of different
materials to RF.
Heat the material in the microwave oven for a short time.
Include a cup of water as a load.
The hotter the material gets, the lossier it is to RF.
I have some bowls the expoded in the microwave oven due to disipation.

>I've got a trunk lip mount and I want to use a 5/8 wave antenna with it.
>If I attach a piece of wire running from the ground of the antenna to a
>suitable ground in the trunk, will this have the same affect as putting
>the antenna on the roof of my car? Thanks.

No. For the current mirror to be effective, it has to be directly
under the antenna. The only way to get top of the car performance
is to mount the antenna on the top of the car. Mounting on the trunk
will result in directional properties because the signal will be
shielded by the cabin to the front, and because the groundplane
under the antenna will be asymmetric. Running a wire inside the
car will have no effect on the antenna pattern. The antenna is
already "grounded" by the trunk lip mount. THe trunk lid is its
groundplane (such as it is).

: >Thanks, Tom Kreyche KG6YJ

In ancient times (during WW2), I was a very junior participant in a super secret AAF project (except that the Japanese, and probably Germans, too, knew all about the subject. A Japanese professor named Kimpara was one of the early investigators during the '30's) to develop a long range storm detector system utilizing radio "static" for triangulation.

Atmospheric static (the project was code-named 'Sferics) propagates best at ultra-low frequencies. We used 10-KHz. Like all low frequency radio waves, they propagate via a ground wave, which rapidly dies out with distance in a square-law manner), and sky wave that travels all around the world. Over salt water, the latter travels in straight lines, and a very simple RDF system will give reliable results over thousands of miles of ocean. The 'Sferics detectors were simple shielded loop antennas, one oriented N-S and the other E-W, tuned to resonance at 10-KHz. Each developed a signal that was amplified by a three-stage amplifier and the raw 10-KHz. outputs were put on the vertical and horizontal plates, respectively, of a CRT. A distant static crash would cause a diagonal line to appear on the scope at an angle equal to the azimuth, to a high degree of accuracy.

The original development used three stations, located at Red Bank, NJ, Palm Beach, FL, and Bermuda. We had BC-610 transmitters and dipole antennas at all three stations. For an observing "run", each station would take turns and one person would watch the scope with a mike in his hand. When he saw a "strike", he would shout "number one" (or two, etc.) into the mike then write down the angle he read. When all three stations had taken turns counting out about 20 "strikes", we would dictate the angles read back to the home station at Red BAnk. There, we had a map board with weighted strings through holes representing the three locations. It was a simple task to pull out the strings at the correct angle for each "stroke" and plot the intersection point of all three bearings.

For a while, I was the observer on a B-17 that flew reconaissance flights covering most of the North Atlantic to verify that the storms detected were actually there. I can testify that they were!

Later, two such "nets" were established in the Pacific. The one I was with had stations in the Philippines area in northwestern Luzon, Samar, Palawan, and Morotai. The central Pacific net was headquartered on Guam, but I don't remember the locations of the other stations.

As soon as the war was over, the project was abandoned because of the amount of manpower it required. Many years later, Paul Ryan realized that local storm detection could be done using the same azimuth detection scheme and estimating the distance by measuring the amplitude of the signal. The amplitude drops off at the square-law rate and the pilot is primarily concerned about the storms nearest to him, so a strong signal means it is close by and he knows to get out of its way, pronto! If the measurement of the distance of another storm farther away is not too accurate, he really doesn't care much. That is the principle of the Ryan StormScope, which has been very successful.
